METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE. — The clinical practice of the hospital comprises a service of 750 beds, of which 676 are in the hospital at Smithfield, and 75 are for convalescent patients at Swanley.

Four house-physicians, ten house-surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. Two qualified assistant electricians are appointed every three months. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

Foundation and other Prizes. — Open Scholarships in Science of the value of £130 each, tenable for one year, will be competed for in September. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, Physiology (not more than four subjects to be taken), and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This exhibition, of the value of £50, is tenable for one year. The examination is confined to students of the hospital of less than six months' standing, and will be held in October.—The Jeaffreson Exhibition, of the value of £20, is awarded after examination in the subjects of General Education. It is now an Open Exhibition.—A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry.—Kirke's Scholarship, and Gold Medal in Clinical Medicine, value 40 guineas. Lawrence Scholarship, and Gold Medal, of the value of 40 guineas (founded in 1873 by the family of the late Sir William Lawrence).—Two Brackenbury Scholarships in Medicine and Surgery, £30 each.—Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

A prize for Anatomy has been founded by the late Mr. Henry Skinner in memory of his brother, and by Miss Shuter in memory of her brother, formerly assistant-surgeon to St. Bartholomew's Hospital.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, £91 10s., if paid in a single sum on entry, or £105 if paid in five instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery, to the new classes of systematic practical instruction in Medicine and Surgery, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Preliminary Science Instruction. — Arrangements have been made for students desirous of undergoing a course of instruction in science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend at the Normal School of Science, South Kensington.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*—English, Latin, Mechanics, and Mathematics; *Optional* (only one of which may be selected)—Chemistry, German or French, the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete, on or before Monday, September 19th, 1887. Two scholarships are open for competition among general students: the Llewellyn Scholarship of £25, for students who have just completed their attendance on lectures; and the Golding Scholarship of £15, for students who have just completed their first year. The Pereira prize of £5 is open to all general students, and is awarded annually for the best clinical reports. The Governor's Gold Medal is given for excellence in clinical work. Silver or Bronze Medals, or an equivalent in books, are awarded to the most distinguished students in all classes; and special prizes in the classes of Dental Surgery, Practical Surgery, and Practical Histology.

ST. GEORGE'S HOSPITAL.—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointment of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, registrar's assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. Gentlemen are admitted to the hospital practice and lectures required by the College of Physicians and Surgeons and the Society of the Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £15 for each subsequent year of attendance. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100.

Entrance Scholarships.—£125, open to sons of medical men; two of £50 each, open to all students commencing their medical studies; £90, open to students who have passed the Cambridge First M.B.; £75, open to students who have been signed up for or passed the Oxford First M.B. or Cambridge Second M.B.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previously to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery.—The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession and for moral conduct, open to perpetual pupils in their fourth year of study.—Sir Charles Clarke's Prize (interest of £200 consols) for good conduct; the Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; the Treasurer's Prize, £10 10s.; the Thompson Medal; the Brodie Prize for Clinical Surgery; the Acland Prize for Clinical Medicine; the Pollock Prize in Physiology; the Henry Charles Johnson Prize in Anatomy; and General Proficiency Prizes, value £10 10s. each, for students of each year.

GUY'S HOSPITAL. — *Appointments:* House-physicians, house-surgeons, obstetric resident assistants, clinical assistants, surgeons' and assistant-surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments, are appointed from among the students, upon the recommendation of the medical staff, according to merit, and without extra payment. The house-physicians, of whom there are three, hold office for six months each, the first two months as third house-physician, another two months as second house-physician, and the last two months as senior house-physician. The third house-physician attends in the Out-patient Department three afternoons in the week, and sees all the cases not seen by the assistant-physician of the day. The second and senior house-physicians have the care of the patients in the Medical Wards, and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the hospital free of expense. The house-surgeons, of whom there are three, hold office for six months each. During the first two months the house-surgeon has the superintendence of the Surgical Casualty Department; for the next two months he has charge of cases in the Special Wards, and assists in the Out-patient Room; and for the last period, as

Digitized by Google

senior house-surgeon, he has the care of the patients in the General Surgical Wards, and is responsible for their treatment in the absence of the surgeons. Except for the first two months, he is provided with board and lodging in the hospital free of expense. The surgeons' dressers are selected from those students who have completed their third winter session, and have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, two in number, are provided with board and lodging in the hospital free of expense.

Scholarships, Prizes, &c.—Entrance Scholarship in Arts £131 5*s*.). Subjects: Latin, Greek, French, German, and Mathematics.—Entrance Scholarship in Science (£131 5*s*.). Subjects: Inorganic Chemistry, Zoology, Botany, Physics. The examination begins on Wednesday, Sept. 28th.—For first-year students: First prize £50, second prize £25, for Anatomy, Physiology, Materia Medica, and Chemistry.—For second-year students: First prize £25, second prize £10, for Anatomy and Physiology. The Sands Cox Scholarship of £15 (tenable for three years) for Physiology. The Michael Harris prize of £10 for Anatomy.—For third-year students: First prize £25, second prize £10, for Medical and Surgical Anatomy, Midwifery, and Therapeutics.—For fourth-year students: First prize £25, second prize £10, for Medicine, Surgery, Midwifery, and Medical Jurisprudence. The Golding Bird prize of £33 for Methods of Diagnosis in Disease.—For senior students: The Treasurer's Gold Medal for Clinical Medicine; the Treasurer's Gold Medal for Clinical Surgery; the Gurney Hoare prize of £25 for Clinical Reports and Commentaries; the Beaney prize of 30 guineas for Pathology; and the Mackenzie Bacon prize of £15 for Nervous Diseases.—The Physical Society awards two prizes, each of £5, to the authors of the best Essays on selected subjects, prizes of £10 and £5 for the best papers read before the Society, and a prize of £5 to the member who has most distinguished himself in the debates of the session.

Fees.—1. A perpetual ticket, including admission to lectures, demonstrations, and hospital practice, competition for prizes, and eligibility for hospital appointments, may be obtained—(*a*) by the payment of 125 guineas on entrance; (*b*) by two payments of £66, one on entrance, the other at the commencement of the ensuing session; (*c*) by the payment of three annual instalments, at the commencement of each academical year: first year, £50; second year, £50; third year, £37 10*s*. 2. A reduction is made in the fees for a perpetual ticket in the case of students who have spent one or more years at another medical school. Students entering as second-year students are charged for their first year at Guy's Hospital, £50; second year, £40; third year, £20; or 95 guineas in one sum on entrance. Students entering as third-year students are charged for their first year at Guy's Hospital, £50; second year, £20; or 65 guineas in one sum on entrance. Students entering as fourth-year students are charged for their first year at Guy's Hospital. £50; second year, £5; or 50 guineas in one sum on entrance.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the ophthalmic clinical assistant, the clinical clerks, and the house-surgeons and dressers, are selected by examination from among those matriculated students of the college who are pupils of the hospital. Rooms are provided within the walls of the College for the residence of a limited number of matriculated students. Rooms and commons are provided at the hospital for the resident officers free of charge.

Scholarships.—Warneford Scholarships: Two of £25 per annum for three years for Literature. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science. Rabbeth Scholarship of £20 per year for Science. College Scholarships: One of £40 per annum for two years; one of £30 for one year; three of £20 for one year. The Daniell Scholarship, for Chemistry, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4*s*. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. Class Prizes, value £3 3*s*. each, are awarded annually in every subject. A Warneford Scholarship of £25 per annum for two years for third-year subjects is awarded annually to resident students only.

LONDON HOSPITAL AND COLLEGE.—The Medical School of the London Hospital has lately been entirely remodelled and rebuilt. The present buildings were opened by their Royal Highnesses the Prince and Princess of Wales on May 21st, the accommodation now afforded being more than double that which was provided in the old buildings. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 8743, out-patients 80,691, and the number of accidents 11,195.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 19th, 20th, and 21st, 1887. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered; and are not eligible to compete for the Buxton Scholarships.—The two Buxton Scholarships, value £30 and £20, will be offered for competition on September 26th, 27th, and 28th, 1887. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination.—A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session by first and second year students.—A Scholarship, value £20, in Anatomy and Physiology for first-year students. (At the commencement of the summer session.)—The Letheby Prize, value £30, for Proficiency in Chemistry. (At the end of the summer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance.—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.)—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Surgery. (At the end of the winter session.)—A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.)—The Duckworth Nelson Prize, value £10, will be offered bienially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery.—The Hutchinson Prize, value £35, will be given triennially to the author of the best essay upon a subject in Clinical Surgery. Candidates must be full students of the hospital who have not been registered more than ten years.—Out-patients' Dressers' Prizes. Six prizes, of the aggregate value of £60, will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons.—Two Dissection Prizes, value £6 and £4.

Special classes are held throughout the year for the Preliminary Scientific Intermediate M.B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c.

In addition to the regular courses of lectures, there will be given during the winter and summer sessions a course of Lectures on Clinical Medicine by Sir Andrew Clark, Bart., F.R.S., Emeritus Professor of Clinical Medicine, and courses of lectures on Clinical Surgery by Mr. Jonathan Hutchinson, F.R.S., Emeritus Professor of Clinical Surgery.

During the summer session a course of lectures will be delivered on Pathological Chemistry by Dr. C. H. Ralfe, Physician to the Hospital, on Mondays, at 4 P.M.

ST. MARY'S HOSPITAL.—There are five resident medical officers, four of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded

Digitized by Google

after competition, without additional fee. Two Demonstrators of Anatomy are appointed annually, with a salary of £70 and £50 respectively; a Demonstrator of Physiology, at £100 a year; and a Demonstrator of Histology, at £50 a year. All these officers are eligible for re-election. There is also a Demonstratorship in Pathological Anatomy, of the value of £15, and tenable for six months; the holder of this scholarship will assist the pathologist in the discharge of duties in the museum and dead-house. Two Prosectors of Anatomy and two Assistant Demonstrators of Physiology are appointed annually, and receive a certificate and £5 each for satisfactory service in their respective departments. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. In addition to the instruction given in the wards daily, distinct Clinical Lectures are given on Fridays throughout the academical year, at 3.30 P.M. The hospital contains 270 beds, 130 of which are devoted to medical and 140 to surgical cases. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases.

Scholarships, Prizes, and Appointments: Scholarships offered for open competition previously to entering at the Medical School.—Entrance Scholarships: The following will be offered for competition on Sept. 30th and Oct. 1st:—One Scholarship in Natural Science, of the value of 100 guineas, open to any gentleman who has not completed a winter session of study at a medical school. Three Scholarships in Natural Science, each of the value of 50 guineas, under the same conditions. One Scholarship of the value of 100 guineas, open to students from Epsom College, being sons of medical men, and who have not completed a winter session of study at a medical school. Two Scholarships, each of 50 guineas, open to students from the Universities of Oxford, Cambridge, or other University, who have not entered at any London medical school.

In addition to the Open Entrance Scholarships, Class Prizes, and usual Appointments, Scholarships will be offered for competition at the end of each year, open to all pupils. These Scholarships are of the value of £20, £25, and £30, for the first, second, and third years respectively.

A residence for students, 33, Westbourne-terrace, W., in connexion with the hospital, is under the charge of a warden, and the Dean is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: 90 guineas for the academical year, to include special instruction by the Demonstrators on three evenings a week.

MIDDLESEX HOSPITAL.—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in Medicine, Midwifery, in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. The museum has recently been rearranged, and a complete catalogue prepared of the various specimens. Two Entrance Scholarships, of the annual value of £50 and £30, and tenable for two years, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10*s.*, is awarded to students at the end of their first year. The Lyell Medal is awarded annually for proficiency in Surgical Anatomy and Practical Surgery. The Hetley Prize is awarded annually for Clinical proficiency. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and in the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1889. The Governors' Prize of 20 guineas is also awarded annually to the student after his third winter session who shall pass the best clinical examination in the out-patient departments. Valuable class prizes are also given, and fourteen resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education and complied with the regulations of the school.

Arrangements have been made for students desirous of undergoing a course of instruction in Science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend such a course at the Normal School of Science, South Kensington. Fee for the whole course, £35. Students who enter for this course will be allowed a deduction of £20 on the fees for the medical curriculum.

A *Residential College*, intended to accommodate about thirty students, and adjoining the medical school, has been erected during the present year. The warden assists the students in their studies.

ST. THOMAS'S HOSPITAL.—*Prizes and Appointments for the year 1887-88.*—For First-year students: Two Entrance Scholarships in Natural Science of the value of 125 guineas and £60 respectively, open to all first-year students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology, at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer £15 and £10. For Second-year students: The Peacock Scholarship of 40 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the students who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes £42, £20, and £10; summer, £15 and £10; with the dresserships and the clinical clerkships. For Third-year students (winter): Second Tenure of Scholarship £42, and prizes of £20, £15, and £10; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £15 annually is awarded to students, who shall be from three to six years' standing, for the best Anatomical or Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal for Surgery and Surgical Anatomy, and the Mead Medal for Practical Medicine, are awarded annually to fourth-year students. The Solly Medal, with a prize of from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical cases. The next award will be made in 1888. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year student.

Classes in Practical and Operative Surgery are held four times a week for six weeks prior to the final examinations of the Examining Board in January, April, and July. In connexion with these classes, Clinical Instruction is given in the wards by the resident assistant-surgeon, and a course of demonstrations on Museum Specimens is given by the curator, Mr. Shattock.

UNIVERSITY COLLEGE, LONDON.—*Composition Fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 120 guineas, if paid in one sum at the commencement of the course; 125 guineas, if paid by instalments, as follows—first year, 55 guineas; second year, 50 guineas; third year, 20 guineas. 2. For those Students who do not require to attend Chemistry, Pharmacy, and Materia Medica at a medical school (under the regulations of the Examining Board in England) the fee will be—100 guineas, if paid in one sum; 105 guineas, if paid by instalments, as follows—first year, 50 guineas; second year, 35 guineas; third year, 20 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 50 guineas. 4. For the course of instruction for the Final M.B. Examination of the University of London, 70 guineas, if paid in one sum; 72 guineas, if paid by instalments, as follows—first year, 40 guineas; second year, 32 guineas. 5. Composition fee for Dental Students, 60 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M.B.) Examination of the University of London, 35 guineas.

Exhibitions, Prizes, &c.—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics,

Digitized by Google

Botany, and Zoology. The next examination will take place at the College on September 29th and 30th. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Charpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Cluff Memorial Prize, value about £15, every second year to the most proficient in Anatomy, Physiology, and Chemistry. The Erichsen Prize: a surgeon's operating case of the value of £10 10s., awarded yearly to the student of the class of Practical Surgery who shall most distinguish himself by manipulative skill. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class.

Residence of Students.—University Hall (Professor Henry Morley, Principal) adjoins the College, and is designed to enable men studying in University College to live in chambers under conditions of fellowship adapted to the needs of modern student life. Full information as to cost and conditions of residence in University Hall may be had by application at the office of the College.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

A curator of the Museum and pathologist, with a salary of 50 guineas, and a medical and surgical registrar, are appointed annually, each with a salary of £40. Two house-physicians, two house-surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons. The senior house-physician, who is also the chloroformist to the hospital, and the senior house-surgeon, who performs special duties, receive in addition an honorarium of 20 guineas each. Clinical assistants to the physicians and surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

Scholarships and Prizes.—The Guthrie and Entrance Scholarship, on alternate years, each £40 a year, and one Entrance Scholarship value £40. Entrance Scholarship, summer session, value £40. The Treasurers' Prize, an exhibition in Anatomy, Physiology, and Chemistry, value £10. 10s., tenable for one year for first-year men. The President's Prize, a Scholarship in Anatomy, Histology, and Physiology, value £21, given by his Grace the Duke of Westminster, President of the Hospital, to a student of the second year (to be styled Assistant Demonstrator). At the end of the fourth winter session, prizes of £5 each (books or instruments) in Clinical Medicine and Clinical Surgery. Frederick Bird Medal and Prize, value £15. Subjects of examination: Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes special prizes, value about 2 guineas each, are given by the lecturers.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road. Consulting Surgeon: Frederick Le Gros Clark. Physicians: Drs. Cholmeley, Cook, Burnet, Beale, and Beevor. Obstetric Physicians: Drs. Gustavus C. P. Murray and Fancourt Barnes. Surgeons: Messrs. W. Adams, W. Spencer Watson, J. Macready, C. B. Lockwood, and A. W. Allingham. Ophthalmic Surgeon: Mr. Jonathan Hutchinson, jun. Aural Surgeon: Mr. W. R. H. Steawart. Chloroformist: Dr. J. F. W. Silk. Dental Surgeon: Mr. E. Keen. House-Surgeon: Mr. A. M. Cowie, M.B. House-Physician: Mr. C. Mortlock. Dispenser: Mr. J. F. Dunstan.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Consulting Physicians: Dr. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S., Dr. J. E. Pollock. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. E. Thompson, and F. Roberts. Surgeon: Mr. R. J. Godlee, F.R.C.S. Assistant-Physicians: Drs. T. H. Green, J. M. Bruce, J. Fowler, P. Kidd, C. Y. Biss, and C. T. Acland. Pathologist: Dr. P. Kidd. Dental Surgeon: Mr. C. J. Noble. Resident Medical Officer: Dr. H. D. Waugh. Secretary: Mr. H. Dobbin. Four Clinical Assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms £3 3s. for three months; six months, £5 5s.; perpetual, £10 10s. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road (established 1814). Consulting Physician: Dr. Horace Dobell. Physicians: Drs. Hensley, Gilbart-Smith, Finlay White, Pringle, and Oswald Browne. Assistant-Physicians: Drs. Arthur Davies, Herbert Habershon, and Edward Stewart. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. A. Pearce Gould. House-Physicians: Messrs. William J. Best, M.R.C.S., L.S.A., and Percy G. Lewis, M.R.C.S., L.S.A. John J. Austin, Secretary. Attendances: In-patients (1886), 305; out-patients (1886), 29,04s. This hospital has recently been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for eighty in-patients.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—The new hospital, with the Finchley branch, contains 180 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patients' practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physicians for out-patients: Drs. H. Charlton Bastian, W. R. Gowers, and D. Ferrier. Assistant-Physicians: Drs. Ormerod and Beevor. Surgeons: Messrs. W. Adams and Victor Horsley. Ophthalmic Surgeons: Messrs. R. Brudenell Carter and Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Dr. Felix Semon. House-Physicians: Messrs. Walter Hull and R. T. Williamson. Medical practitioners and senior students may attend the practice after signing their names in the clerk's office.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804, and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by 2049 persons. The out-patients are yearly over 20,000; attendances, 123,555 in 1886. Operations are performed daily from 10.30 to 1 o'clock, and three surgeons attend on each day. Students are admitted to the practice. Fees for six months, £3 3s.; perpetual £5 5s. Demonstrations and lectures are given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants. The secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at 2 o'clock. The following are the days of attendance of the surgeons: Mr. Power and Mr. Frost, Monday and Friday; Mr. Rouse and Mr. Hartridge, Tuesday and Saturday; Mr. Macnamara, Monday and Thursday; Mr. Cowell, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special demonstrations and lectures will be given during the session. Secretary: Mr. T. Beattie-Campbell.

ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. Assistant-Surgeon: Mr. H. F. Baker. House-Surgeon: Mr. E. H. Norris. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils

Digitized by Google

are admitted to witness the practice of the hospital on the following terms: six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry by Dr. J. Walker, on Wednesdays at 5 P.M. In summer, by Mr. Hutchinson, on Dental Surgery and Pathology, on Tuesdays and Fridays at 8 A.M., and by Mr. Arthur Underwood, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. *Fees:* General fee for special lectures required by the curriculum, £15 15s.; fees for two years' hospital practice required by the curriculum, £15 15s.; total fees for lectures and practice, £31 10s. Hospital Surgeons: Messrs. Canton, Gregson, Hepburn, Storer Bennett, Claude Rogers, and Woodhouse. Assistant-Surgeons: Messrs. Hern, Matheson, Parkinson, Read, Rogers, Truman, and E. Lloyd Williams. Anæsthetists: Messrs. Braine, Bailey, Bird, and Mills. Assistant-Anæsthetists: Drs. Buxton and Hewitt. House-Surgeon: Mr. H. Williams. Assistant House-Surgeons: Messrs. F. Colyer and G. Seymour. Medical Tutor: Mr. W. Paterson. The winter session will commence October 4th. All communications to be addressed to Mr. Morton Smale, Dean.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich, S.E.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students. Honorary Consulting Physicians: Dr. Robert Barnes, F.R.C.P., and Dr. Richard Quain, F.R.C.P. Visiting Physicians: Dr. John Curnow, F.R.C.P., and Dr. Herbert Tyrrell Griffiths, M.R.C.P. Honorary Consulting Surgeon: Mr. J. N. Davies-Colley, F.R.C.S. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Medical Officer, Well-street Dispensary: Mr. C. E. Cotes, F.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. House-Physician: Dr. E. H. Booth. House-Surgeon: Mr. R. Ritson, M.R.C.S. Secretary: Mr. P. Michelli.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen's-square, W.C., and Cromwell House, Highgate.—There are now 121 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total, 173. In-patients last year, 1144; out-patients, 14,287. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physicians: Dr. G. O. Rees, Dr. Gream, Dr. Brodie. Consulting Surgeons: Mr. H. Lee, Sir William Mac Cormac. Physicians to In-patients: Dr. Hope and Dr. W. C. Grigg. This hospital, which has been recently enlarged, receives nearly 1000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all universities, colleges, and licensing bodies. Monthly nurses and midwives are received for training. Fees: Medical students, from £3 3s. for one week, to £26 5s. for three months, exclusive of board and lodging; Pupil Midwives, £26 5s. for three months, and Pupil Nurses, £11 0s. 6d., for eight weeks, both inclusive of board and lodging. For further particulars, application should be made to G. Owen Ryan, Esq., Secretary, at the hospital.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road.—Instituted 1816. Consulting Physicians: Dr. Wilks and Dr. John Williams. Consulting Physician: Dr. Wm. Park. Physicians: Drs. W. A. Duncan, Alex. Haig-Septimus Sunderland, and W. R. Dakin. Surgeon: Mr. H. C. Jacobson. Assistant-Surgeon: Mr. E. Overman Day. Surgeon-Dentist: Mr. W. Whitehouse. Resident Medical Officer: G. W. Moseley. Secretary: Mr. R. G. Kestin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

HOSPITAL FOR WOMEN, Soho-square, W.—Consulting Physician: Dr. Protheroe Smith. Physicians: Drs. Carter, Richard T. Smith, Holland, and Mansell-Moullin. Surgeon: Mr. H. A. Reeves. Assistant-Physicians: Drs. Bedford Fenwick and Oliver. Assistant-Surgeon: Mr. S. Osborne. Pathologist and Registrar: Dr. Norman Dalton. Anæsthetist: Dr. Dudley Buxton. In connexion with this institution there has been for some years a well-organised Clinical Department, which has lately been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women, ten gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients; The appointments are nominally "open to qualified medical men and to students of medicine after their third year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large numbers of out-patients afford quite unrivalled opportunities for practical instruction in the use of gynæcological instruments, and for the study of diseases peculiar to women. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter by a member of the Staff. Clinical Lectures are given in the Operating Theatre on alternate Thursdays, at 3.30 P.M., throughout the winter and summer sessions. Valuable prizes are given, after examination, annually, open to past and present clinical assistants. Fee for the three months' course, £5 5s. Any further information can be obtained by letter, addressed to the Dean at the hospital.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The hospital contains 60 beds and 12 at the home at Margate, and has a large out-patient department (over 500 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physicians to the out-patients: Drs. Albert Venn, T. Colcott Fox, F. D. Drewitt, and Henry Philpot. Surgeons: Messrs. Pick and Clutton. Surgeons to the out-patients: Messrs. Walter Pye and D'Arcy Power. Dental Surgeon: Mr. Francis Fox. House-Surgeon: Cameron Kidd. House-Physician: Alexander Harper. Secretary: Captain W. C. Blount, R.N. Out-patients are seen daily as under:—Medical cases: Monday only at 9A.M.; and every afternoon at 1.30. Surgical cases: Daily, except Wednesday and Saturday, at 9.30 A.M. Dental cases: Saturdays at 9 A.M.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Consulting Physicians: Dr. Robert Barnes and Sir Andrew Clark, Bart., M.D. Consulting Surgeon: Mr. Buxton Shillitoe. Consulting Ophthalmic Surgeon: Mr. George Cowell. Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, and Dr. H. Radcliffe Crocker. Surgeons: Mr. Arthur Cæsar and Mr. R. W. Parker. Assistant-Surgeon: Mr. L. A. Dunn. Assistant-Physicians: Dr. J. A. Coutts and Dr. Dawson Williams. Administrator of Anæsthetics: Mr. Thomas Bird. Resident Medical Officer: Mr. J. Scott Battams. Secretary: Ashton Warner. Lady Superintendent: Miss F. A. Davies. Matron: Mrs. Fisher.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 110 beds. About 1100 in-patients and 14,000 out-patients, whose attendances number nearly 50,000, are treated annually. There are appointments for a House-Physician and two House-Surgeons, with board and residence, tenable for six months. Also appointments for a limited number of Clinical Assistants. Physicians: Drs. G. Goddard Rogers, D. W. C. Hood, and F. G. D. Drewitt. Physician for Diseases of Women: Dr. Albert Venn. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and W. Bruce Clarke. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant-Physicians: Drs. W. P. Herringham, J. B. Ball, and Seymour Taylor. Assistant-Physician for Diseases of Women: Dr. J. A. Mansell-Moullin. Assistant-Surgeons: Messrs. C. A. Ballance, H. F. Weiss, and B. Wainwright. Assistant-Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. L. Albert. Pathologist: Mr. H. P. Dunn. Physician in Charge of Throat Department: Dr. J. B. Ball. Aural Surgeon: Mr. B. Wainwright. Physician to Skin Department: Dr. F. G. D. Drewitt. Surgeon to Skin Department: Mr. H. F. Weiss. Surgeon in Charge of Orthopædic Department: Mr. C. B. Keetley. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Secretary: Mr. R. J. Gilbert.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeons: Sir Prescott G. Hewett, Bart., and Mr. W. Morrant Baker. Physicians: Drs. Fred. Taylor, James F. Goodhart, Nestor Tirard, and Fred. Willcocks. Surgeons: Messrs. H. G. Howse, R. Clement Lucas, C. J. Symonds, and G. H. Makins. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. R. Denison Pedley. House-Surgeon: Dr. Geo. A. Carpenter. Hon. Secretary: Dr. I. Dobree Chepmell.

ALL SAINTS CHILDREN'S HOSPITAL, 4, Margaret-street, and 59, Mortimer-street, W. — Founded by the All Saints Sisterhood in 1882 for Chronic Joint Diseases. Twelve beds for boys and eight for girls under the age of ten years. Surgeon, Mr. Noble Smith.

MR. THOMAS COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, SURGERY, &c.—By decision of the Royal Colleges of Physicians and Surgeons, gentlemen rejected at their Anatomical and Physiological Examinations (Primary R.C.S., or Second Conjoint) can get "signed up" from this school for the three or six months' work they are now required to put in before re-examination. This school is intended to meet the requirements of two classes of students: 1. Qualified practitioners and advanced students—i.e., gentlemen wishing either to obtain some of the higher qualifications, or to compete for appointments in Her Majesty's Army, Navy, and Indian Medical Services. 2. Students preparing for the usual Primary and Pass Examinations of any of the licensing bodies. The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological and surgical apparatus, splints, &c. The school possesses a good collection of physiological apparatus, allowing of the demonstration to the class of the great bulk of the usual practical exercises in Physiology; also chemical apparatus, allowing every student not only to see, but to repeat for himself, the analysis of the principal food-stuffs, and fluids and solids of the body, and also all the usual reactions, tests, &c. Gentlemen preparing for the Higher Examinations receive special instruction in the more difficult subjects, and have the advantage of personally repeating the practical exercises in Physiology above alluded to. The operations of surgery are performed by the students on the dead body. Private address: 40, Brunswick-square.

SOUTH LONDON SCHOOL OF PHARMACY.—This school was established in 1868, and removed to the present premises in 1875. Owing to the expiration of the lease at the old premises, it has recently been joined by the analytical and general science teaching branches previously carried on at Kennington-cross, and the whole institution is now consolidated under one roof, so bringing every department under the continuous and direct control of the director, Dr. John Muter, M.A., F.R.S.E., F.C.S., F.I.C., who personally delivers the lectures on Chemistry, Physics, and Botany, and superintends the laboratory instruction. The department most valuable to medical Students is the Medical and General Science Tutorial Department. The subjects taught are:—For Matriculation, &c.: Elementary Chemistry. For First B.Sc. and Preliminary Scientific: Inorganic and Practical Chemistry. For First M.B.: Organic Chemistry, Analysis, and Pharmaceutical Chemistry and Materia Medica. For Apothecaries' Hall and Royal Colleges of Physicians, London and Edinburgh: Chemistry, Botany, and Materia Medica. For Pass M.B. Lond: Practical Toxicology and Forensic Medicine. Students attend by special arrangement, and perpetual or time fees may be had from the Secretary, Mr. Baxter, 325, Kennington-road, London, S.E.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures on Chemistry and Physics by Professor Dunstan, F.C.S.; Practical Chemistry, Professor John Attfield, Ph.D., F.R.S., F.I.C., F.C.S., Director of the Laboratories; F. W. Short, Demonstrator; Botany, by Professor Green, B.A., B.Sc.; Materia Medica, by Mr. Holmes, F.L.S.; Practical Pharmacy, Joseph Ince, F.L.S. The session commences on Monday, Oct. 3rd, at 9 A.M. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures, &c., and to a course of practical chemistry of any length in the laboratories. Application for admission to the school, or for further information, may be made to the professors or their assistants in the lecture theatre or laboratories, 17, Bloomsbury-square, London, W.C.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—120 beds. Honorary Consulting Physician: Dr. Coates. Honorary Physicians: Drs. Goodridge, Cole, and Fox. Honorary Surgeons: Messrs. Stockwell, Fowler, and Freeman. Honorary Medical Officers for Out-patients: Dr. Field, Messrs. Cowan and Craddock. Honorary Assistant-Surgeons: Messrs. Green, Scott, and Ransford. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Culliford-Hopkins. The hospital is recognised by the Royal College of Physicians, Surgeons, &c., and licensed for dissections. It contains a library and an excellent museum, in which are a large number of interesting specimens, both in Pathology and Comparative Anatomy. Fees for attendance—twelve months, £10 10s.; six months, £5 5s. (Temporary pupils can also, by permission of the Honorary Staff, attend the practice of the Hospital by the payment of £1 1s. for each month.) Instruction in Practical Pharmacy for three months, £5 5s. Number of patients admitted during the past year, 1106; out-patients, 8758. Operations performed, 158. Anæsthetics recorded, 195. For further particulars apply to the Registrar and Curator.

QUEEN'S COLLEGE, BIRMINGHAM.—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. Two Ingleby Scholarships are offered annually after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. The Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually, of the value of 30 guineas. They are held for three years, one-third being paid each year, subject to good behaviour. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. Students of Queen's College are qualified to compete for all scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

GENERAL AND QUEEN'S HOSPITALS, BIRMINGHAM. — *General Hospital:* Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Wade, Foster, Rickards, and Saundby. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Simon and Foxwell. Assistant-Surgeons: Messrs. Haslam and Barling. — *Queen's Hospital:* Consulting Obstetric Surgeon: Mr. Berry. Consulting Surgeon: Mr. S. Gamgee. Physicians: Drs. Sawyer, Carter, and Suckling. Surgeons: Messrs. Furneaux Jordan, Wilders, Bennett May, and Lloyd, Obstetric Surgeon: Mr. A. F. Hawkins. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Physician for Out-patients: Dr. Hogben. Casualty Surgeons: Messrs. Clay and Marsh.

MASON COLLEGE, BIRMINGHAM.—Founded 1875. Opened 1880. The session will commence on October 3rd. Instruction is given in Arts and Science, and students are prepared for the various examinations of the University of London. Entrance and other Scholarships and Prizes are offered for competition. This College is associated with Queen's College, Birmingham, for the purposes of medical education, all students of the latter College attending in the Physical, Chemical, Zoological, Botanical, and Physiological Departments of Mason College. The Library contains upwards of 18,000 volumes. A syllabus containing full information as to the various courses of instruction, fees, &c., will be forwarded on application to the Secretary.

BRISTOL SCHOOL OF MEDICINE (affiliated to University College, Bristol).—Students can complete in Bristol the entire course of study required for the Medical and Surgical Degrees of the University of London, and for the Diplomas

Digitized by Google

of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given at University College, Bristol, are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; while the Medical School, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the Dean of the Bristol Medical School, Dr. Markham Skerritt.

BRISTOL ROYAL INFIRMARY (instituted 1735).—264 beds. Physicians: Drs. Spencer, Shingleton Smith, Waldo, and Shaw. Surgeons: Messrs. Board, Dowson, Prichard, Greig Smith, and Harsant. Ophthalmic Surgeon: Mr. Cross. Assistant-Physician: Dr. Prowse. Assistant-Surgeon: Mr. Paul Bush. House-Surgeon: Dr. Swain. House-Physician: Dr. Williams. Secretary: Lieut.-Colonel Graham.

Scholarships and Prizes.—Two Entrance Scholarships, 85 guineas and 10 guineas, awarded annually in October, after examination in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clarke Prize, 15 guineas; Crosby Leonard Prize, 7 guineas; Tibbitt's Prize, 9 guineas; three Pathological Prizes, 3 guineas each.

Dressers reside in the house in weekly rotation, and have charge of all casualties under the supervision of the house-surgeon. Special instruction (including dresserships) for first-year students in the out-patient department. Class instruction in the wards by the physicians and surgeons on four days a week, in addition to the regular clinical lectures. Clinical Clerkships and Dresserships, 5 guineas for each six months. Special departments for Diseases of Women, the Eye, Ear, &c., with Clerkships and Dresserships attached. A Pathological Clerk is appointed every four months, who performs all post-mortem examinations. The large museum and well-stocked library are arranged and managed for the advantage of students.

Further information can be obtained from Dr. Spencer, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—164 beds. Physicians: Drs. Markham Skerritt, Harrison, and Baron. Physician-Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, Keall, and Pickering. Dentist: Mr. Parson. House-Surgeon: Dr. Newnham. Physicians' Assistant: Mr. Webb. Assistant Physician: Dr. Clarke. Assistant Surgeon: Mr. Penny. Assistant House-Surgeon: Mr. Barclay. Clinical Clerkship, six months, £5 5*s.* Dresserships, six months, £5 5*s.* Obstetric Clerkship, three months, £3 3*s.* Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women and in Dental Surgery. Further information may be obtained of the Secretary, at the hospital, or from Dr. Markham Skerritt, Dean of the Hospital Faculty.

Scholarships and Medals.—Lady Haberfield Entrance Scholarship: This scholarship, founded in 1875, of the value of 30 guineas, the interest of £1000, bequeathed for the purpose by the late Lady Haberfield, is awarded annually at the commencement of the Winter Session, after a competitive examination in subjects of general education. Second Entrance Scholarship: An additional Entrance Scholarship of the value of £20 is awarded when more than six candidates present themselves. Clarke Scholarship: A Surgical Scholarship, of the value of £15, founded by H. M. Clarke, Esq., of London, is awarded annually at the end of the Winter Session, after an examination in Surgery. Sanders Scholarship: A Scholarship founded by the late John Nash Sanders, Esq., of the value of £22 10*s.*, is awarded annually at the end of the Winter Session, after examination in Medicine, Surgery, and Diseases of Women. Martyn Memorial Pathological Scholarships, founded in 1878, by public subscription, in memory of the late Dr. Samuel Martyn, Physician to the Hospital. Two Scholarships, each of the value of £10, are awarded annually; one at the end of the Summer Session, and one at the end of the Winter Session. A student may, at the option of the Faculty, hold both these Scholarships. After a competitive examination in Pathology and Morbid Anatomy, the successful candidate is appointed Pathological Clerk to the Hospital for the term of six months. Committee Gold Medal: This medal, presented by the Committee of the Hospital, is awarded annually at the end of the Winter Session to the student of the fourth year who has most distinguished himself during his career at the Hospital and the Medical School. Committee Silver Medal: This medal, presented by the Committee of the Hospital, is awarded annually at the end of the Winter Session to the next most distinguished student of the fourth year. The rules relating to the several Scholarships may be had on application.

ADDENBROOKE'S HOSPITAL, Cambridge.—Clinical lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. Lewis Shapter and H. Davy. Consulting Surgeons: Messrs. A. Cumming and T. W. Caird. Surgeons: Messrs. Blankart, Harris, Domville, and Bell. House-Surgeon: Dr. Blomfield. The hospital contains 214 beds (including special children's wards). There is a good library, museum, dissecting and post-mortem rooms. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. For further particulars as to fees, &c., apply to the House-Surgeon.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Surgical Staff: Messrs. Bankart and Toswill. Registrar: Mr. Roper. The infirmary contains fifty beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:—A University of Durham Scholarship, value £100, for Proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value £15, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value about £35, for Medicine. The Gibb Scholarship, value £25, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value about £15, for Clinical Medicine and Clinical Surgery. At the end of each session a Silver Medal and Certificates of Honour are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, two Prosectors, and two Assistant Physiologists are elected yearly. Two Pathological Assistants, two Assistants to the Dental Surgeon, and two Assistants in the Eye Department are also elected every three months. Medical and Surgical Assistants, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-ON-TYNE INFIRMARY.—Physicians: Drs. Philipson, Drummond, Oliver, and Limont. Surgeons: Drs. Arnison, L. Armstrong, Hume, and Mr. Page. Assistant-Surgeons: Mr. T. A. Dodd and Mr. Williamson. Pathologist: Dr. Drummond. Dental Surgeon: Mr. E. Fothergill. House-Physician: Dr. Edward Cave. House-Surgeons: Dr. W. Raigent and Dr. W. G. Richardson. The infirmary contains 280 beds. There are special wards for the treatment of Children, and for Ophthalmic and Syphilitic Diseases. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given as opportunity offers by the Pathologist. Practical Midwifery can be studied at the Newcastle Lying-in Hospital, where there is an out-door practice of about 300 cases annually. Lectures are given on Psychological Medicine at the Coxlodge Lunatic Asylum by Dr. R. H. B. Wickham, Medical Superintendent. A Special Course of Instruction is given in the Hospital for Infectious Diseases by the Superintendent and City Officer of Health, Dr. H. E. Armstrong.

GENERAL KENT AND CANTERBURY HOSPITAL.—Open for the reception of patients April 26th, 1793. 49,499 in-patients and 88,792 out-patients have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury

Digitized by Google

Medical Society, for £7 7s. Operation day, Thursday, 11 A.M. Consulting Physician: Dr. Alfred Lochee. Physician: Dr. Henry Alex. Gogarthy. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles Holttum, Frank Wacher, T. Whitehead Reid, and John Greasley. Dentist: Mr. Martin L. Bell. House-Surgeon: Mr. Z. Prentice. Assistant House-Surgeon and Dispenser: Mr. William P. Barrett. Secretary: Mr. Charles H. Read. Over 800 in-patients, 3000 out-patients, and 1000 dental cases are attended in a year.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 320 in-patients, surgical and medical, and during the last year 4428 in-patients and 30,985 out-patients were treated; these numbers show a remarkable increase, if compared with statistics of ten years ago, when only 11,500 out-patients were seen. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in the operating-room. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students.

The Leeds Medical School, now the Medical Department of the Yorkshire College, occupies a central position in the town, close to the General Infirmary, and a few minutes' walk from the new buildings of the Science and Art Departments situated in College-road. The present premises were built specially for the purposes of a medical school, and the teaching in purely medical subjects is there given. The teaching in Chemistry and Physics, Practical Chemistry, Practical Toxicology, Biology, and Botany is given in the College-road buildings, the lecture-rooms and laboratories of which are amongst the most commodious in the kingdom. The accommodation for teaching comprises all the conveniences necessary for the various branches of study. All the other courses required by examining boards are given by Professors and Lecturers. The Museums and Library offer special advantages. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students: Resident medical officer, resident surgical officer, resident obstetric officer, appointed for twelve months and eligible for re-election. Two house-physicians, holding office for six months; four house-surgeons, for twelve months; twenty-four physicians' clerks, for three months; twenty-four surgeons' dressers, for six months; eight ophthalmic and aural surgeons' dressers, for three months; eight gynæcological ward clerks, for three months; eight gynæcological out-patient clerks, for three months; twenty-four assistant-physicians' clerks, for three months; twenty-four assistant-surgeons' dressers, for three months; forty-eight dressers in the casualty-room, for three months; twelve post-mortem room clerks, for three months.

There are appointments open to students in other medical institutions in the town, and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL, MEDICAL FACULTY: VICTORIA UNIVERSITY.—The Infirmary attached to the School contains 300 beds, with 40 special beds for the treatment of Diseases of Women. Lock, Lying-in, and Eye and Ear Hospitals are in the immediate vicinity, and their practice is open to the students of the Medical Faculty.

The composition fee for lectures and classes is 60 guineas, which may be paid in two equal instalments with an interval of twelve months; and for hospital practice 40 guineas, which may be paid in the same way.

Two house-physicians and three house-surgeons are appointed from the qualified pupils every six months, also clinical clerks, dressers, and post-mortem clerks.

Two Holt Tutorial Scholarships, each of the value of £100, are awarded annually by the Medical Faculty to senior students. Also an entrance Lyon Jones Scholarship of £21 for two years for students proceeding to the Victoria Degree, and another of the same value, open to all students who have completed their second year. The Derby Exhibition of £15 for Clinical Medicine and Surgery. The Torr and Bligh Gold Medals for Anatomy and Physiology, and the class prizes. During the past year the new Chemical Laboratories have been opened, and the old building added to the Physiological Department. The only changes on the staff are the appointment of Mr. Edgar Browne as lecturer on ophthalmology, Dr. Hope as lecturer on Hygiene, and Dr. Ross as Demonstrator of Anatomy.

LIVERPOOL NORTHERN HOSPITAL.—150 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Paul. Senior House-Surgeon: Dr. F. H. Wigmore. Junior House-Surgeons: Mr. J. R. L. Dixon and Mr. W. C. Helme. 200 beds. Clinical Lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships are open to all students. Special wards for accidents and diseases of children. Resident students received.

NORFOLK AND NORWICH HOSPITAL. — 150 beds. One year's attendance recognised by examining boards. Fees: For the physicians' practice, 5 guineas for six months. For the surgeons' practice, including dresserships, £10 for three months; £15 for six months; £20 for one year; £30 for two years. Pupils resident and non-resident. Physicians: Sir Peter Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. H. Chester Nance.

NORTHAMPTON GENERAL INFIRMARY.—Established 1743: rebuilt 1793. In-patients, 1693; out-patients, 8223. Beds. 144. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, a great extension of the school buildings has been made. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the medical school and infirmary. The following scholarships and prizes are open to students of the medical school:—1. A Dauntesey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose age does not then exceed twenty-five years. The subjects of examination are—(*a*) General and Comparative Anatomy; (*b*) Physiological Botany; (*c*) Chemistry; (*d*) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the Physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. 4. Two Platt Exhibitions of the value of £15 each, to be competed for by first and second year students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Turner Medical Prize, £25. 7. Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY.—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, H. Browne, and Sir Wm. Roberts. Consulting Surgeons: Mr. Geo. Bowring and Mr. Lund. Physicians: Drs. Henry Simpson, John E. Morgan, D. J. Leech, and J. Dreschfeld. Assistant-Physicians: Drs. James Ross and Graham Steell. Obstetric Physician: Dr. Lloyd Roberts. Surgeons: Messrs F. A. Heath, Walter Whitehead, Thomas Jones, and James Hardie. Assistant-Surgeons: Messrs. Fred. A. Southam and G. A. Wright. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. Ernest S. Reynolds. Resident Surgical Officer: Mr. Joseph Collier. Medical Registrar: Dr. J. S. Bury. Surgical Registrar: Mr. W. Thorburn. Pathological Registrar: Dr. Thomas Harris. Assistant Medical Officers: Drs. S. Moritz and A. T. Wilkinson. Administrator of Anæsthetics: Mr. Alexander Wilson. General Superintendent and Secretary: Mr. W. L. Saunder.

BARNES CONVALESCENT HOME, Cheadle, Cheshire (in connexion with the Manchester Royal Infirmary).—Resident Medical Officer: Mr. E. T. Milner, M.B. Secretary: Mr. W. L. Saunder.

MONSALL FEVER HOSPITAL, Newton Heath (in connexion with the Manchester Royal Infirmary).—Resident Medical Officer: Dr. H. Falconer Oldham. Assistant Medical Officer: Mr. H. Leader Williams. Secretary: Mr. W. L. Saunder.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Special classes are held for clinical instruction on Saturday afternoons during the winter months. Out-patients are seen daily at 9 A.M. at the dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. Assistant-Surgeon: Mr. Joseph Collier. During 1886 there were 1166 in-patients and 10,158 out-patients under treatment at the dispensary.

RADCLIFFE INFIRMARY, OXFORD.—This infirmary is open to students for Medical and Surgical work in the wards and out-patients' departments. Clinical lectures are given by the Litchfield Clinical Lecturer in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination, or the 1st Oxford M.B.

SHEFFIELD SCHOOL OF MEDICINE.—The infirmary contains 180 beds, a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. The Public Hospital and Dispensary contains 101 beds, and is recognised by the Examining bodies. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. A tutor's fee of £2 2s. is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the hospital, and be supplied with cases of midwifery.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan has accommodation for over 200 patients, including children's wards and special ovarian wards. In-patients last year, 1666; out-patients, 9209. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Drs. J. T. Arlidge and C. Orton, and Messrs. Ashwell and J. G. West. Surgeons: Messrs. W. H. Folker, J. Alcock, and W. D. Spanton. Dental Surgeon: Mr. W. Bartlett. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees &c. may be obtained.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Founded 1848. Beds, 224. A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock, and practitioners are welcomed.

YORK COUNTY HOSPITAL.—Established 1740; rebuilt 1851. 116 beds. In-patients, 1127; out-patients, 7171. Consulting Physician: Dr. W. Matterson. Consulting Surgeon: Mr. W. D. Husband. Medical Officers: Messrs. R. Heweteon, W. H. Jalland, F. Shann, R. Turner, M.B., and R. Petch, M.B. Dental Surgeon: Mr. W. Glaisby. House-Surgeon: Mr. E. F. Morris. Assistant House-Surgeon: Mr. Lancelot Williams. Secretary: Mr. R. Holtby.

SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London and Dublin, and the other Medical and Public Boards. In accordance with the Statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three-months' courses. The regulations require that the fee for any class, taken for graduation in Edinburgh, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

Fees.—For a first course of lectures, £3 5s.; for a second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh the perpetual fee is £2 4s. Practical Anatomy (six months' course), £3 3s.; course of demonstrations, £2 2s.; perpetual, £4 4s. Practical Anatomy with course of demonstrations, £4 4s. Practical Chemistry, £3 3s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy, Diseases of the Ear, Diseases of the Skin, Diseases of Children, and Diseases of the Tropics and Climatology, each £2 2s. Vaccination, £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine and Medical Diagnosis, each £2 2s. Insanity, £1 1s.

EDINBURGH SCHOOL OF MEDICINE AND PHARMACY, Marshall-street, Nicolson-square.—The classes of this school will be resumed for the winter session in October. Chemistry, Midwifery, Surgery, and Medicine. From the Dispensary attached to this institution, Pharmacy, Practical and Theoretical. Practical Midwifery. Out-door Practice. Medical and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other licensing boards. Tutorial classes in all the branches of the medical curriculum. Preliminary Medical Classes, 11 A.M. to 4 P.M., and in the evening. Particulars of R. Urquhart, Secretary.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, and Larynx. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, also to cases of Incidental Delirium or Insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 2s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house

Digitized by Google

free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the pathological department are appointed by the pathologists.

ANDERSON'S COLLEGE MEDICAL SCHOOL, GLASGOW.—The following courses are given, which qualify for all the licensing boards:—In winter: Anatomy, Chemistry, Physiology, Surgery, Medicine, Materia Medica, &c. In summer: Midwifery, Medical Jurisprudence, Botany, Hygiene, &c. The Chemical Laboratory is open daily from 10 to 5. Students of the School are admitted to the Lectures and Clinique at the Ophthalmic Institution free of charge.

Fees.—Each course of lectures (except Anatomy), first session, £2 2*s.*; second session, £1 1*s.*; afterwards free. Anatomy (including dissecting-room), first session, £4 4*s.*; second session, £4 4*s.*; third session and perpetual, £1 1*s.*; summer (including Practical Anatomy), £2 2*s.* Practical Anatomy only, £1 1*s.*; Osteology, £1 11*s.* 6*d.* Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at reduced fees Fees for all the Lectures and Hospital practice required of candidates for triple qualification, £48.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session will open on October 26th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures and demonstrations are also given on Public Health, Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, Diseases of the Eye, and of the Throat and Nose. During summer lectures on Insanity are given by Dr. A. Robertson, in the City Asylum under his charge.

Class Fees.—For each course, first session, £2 2*s.*; second session, and perpetual, £1 1*s.*; Anatomy: First winter session, £4 4*s.*; summer session, £1 11*s.* 6*d.*; second winter session, £4 4*s.*; afterwards the fee for lectures and practical anatomy is £1 11*s.* 6*d.* per session. Lectures on Diseases of the Ear, £1 1*s.*; with clinique to those not students of the hospital, £2 2*s.* Dental Dispensary free to students of the hospital; to others, £5; first year, perpetual, £10. Lectures on the Eye £1 1*s.*; other special courses free.

GLASGOW ROYAL INFIRMARY.—Number of beds. 542. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of Venereal Diseases and the Diseases of Women, whilst Diseases of the Skin, Eye, Ear, Throat, and Teeth are specially treated at the Dispensary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons; instruction in Pathological Anatomy and Histology is given by the pathologist.

Appointments.—There are four physicians' and six surgeons' assistants. These appointments are free, and can be held for twelve months; they are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

Fees for Hospital Practice and Clinical Lectures.—First year, £10 10*s.*; second year, £10 10*s.*; afterwards free. For six months, £6 6*s.*; three months, £4 4*s.* Vaccination certificates, £1 1*s.*

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Thursdays, and Fridays, at 2 P.M., by Dr. Barr and assistants; and operations and special demonstrations to students and practitioners take place on Thursdays from 3 to 4 P.M.

GLASGOW WESTERN MEDICAL SCHOOL, University-avenue, Hillhead.—The school is situated close to the Western Infirmary, where students obtain their Hospital Practice and Clinical Lectures. To accommodate the increasing number of students, the dissecting rooms have been recently entirely rearranged and enlarged. The attention of students is directed to the unusual facilities presented for the study of Practical Anatomy and Operative Surgery, the supply of subjects being practically unlimited. The dissecting rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow in accordance with the regulations, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, first session, £2 2*s.*; second session, £1 1*s.* Students who have attended a first course elsewhere pay £1 1*s.* Anatomy, including Practical Anatomy, £4 4*s.* Summer session, £1 11*s.* 6*d.*

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Cutaneous Affections. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department a systematic course is given in the winter and a practical course in the summer; these are likewise recognised by the University for graduation. Eight resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second years; for six months, 7 guineas; and for three months, 4 guineas.

GLASGOW HOSPITAL FOR SICK CHILDREN, situated at Garnet-hill, was opened in December, 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 57 beds for non-infectious cases only.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street.—40 beds. Clinical and systematic course of lectures for students during the winter and summer seasons.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, Angus Fraser, and P. B. Smith. Surgeons: Messrs. A. Ogston, J. O. Wall, R. J. Garden, and Hall. Dental Surgeon: Dr. Williamson. Treasurer and Secretary: Mr. W. Carnie.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains about 580 beds. Consulting Physician: Dr. Robert Jamieson. Clinical instruction is given to students during three months in summer.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Eight Junior Scholarships have been founded in the Faculty of Medicine, of the annual value of £25 each. Two are tenable by Matriculated Students, commencing the first, second, third, and fourth year of their course respectively. The examinations for Junior Scholarships of the second and third years in the Faculty of Medicine take place at the commencement of the second and third year of their medical course. Matriculated Students in Medicine intending to compete for Medical Scholarships of the second year must be of not more than one year's standing as students of Medicine, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, two at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated students in Medicine intending to compete for Medical Scholarships of the third year must be of two years' standing and not more, and must have attended, in some of the Queen's Colleges or in a University capable of granting degrees in Medicine, four at least of the following courses—viz.: Chemistry, Botany and Zoology, Anatomy and Physiology, Materia Medica and Pharmacy, Practical Chemistry, Practical Anatomy. Matriculated Students in Medicine intending to compete for Medical Scholarships of the fourth year must be of three years' standing and not more, and must, in addition to the qualifications prescribed above, have attended, in their

Digitized by Google

third year, two at least of the following courses—viz.: Theory and Practice of Medicine, Theory and Practice of Surgery, Midwifery, and Diseases of Women and Children.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £80 each), as well as several exhibitions and class prizes, are awarded every year.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—The payment of £3 3*s.* to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by the University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre at 10 o'clock on Mondays and Tuesdays. In addition to the hospital fee, the payment of a fee of £9 9*s.* is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12*s.*

Sir Patrick Dun's Maternity.—Total fees for college students, £3 3*s.* Total fees for externs, £6 6*s.*

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance £12 12*s.*; six months', £8 8*s.* Summer, three months', £5 5*s.* Three resident pupils are selected half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, and Gynæcology.

The certificates of attendance are recognised by all the universities and licensing bodies in the United Kingdom.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons; and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this school, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This school is in a central situation, and is replete with every convenience for study and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Woman and Children, one for Diseases of the Eye and Ear, &c.

Returns for the session 1887-8 have not been received from this school.

CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships &c. are awarded to students entering for an *annus medicus* for the current year:—The Carmichael Scholarship, value £15; the Maine Scholarship, value £15; also Lecture Prizes, value £3 and £2 each; £97 being given annually in prizes.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways, and owing to its position affords exceptional advantages for clinical instruction. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Teeth, and those peculiar to Women.

The hospital is visited daily at 8.30 A.M. by the resident surgeon, and at 9 A.M. by the physicians and surgeons. The surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants, who, in addition to their rooms and furniture, are provided with coals and gas.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: Winter, six months, £21; summer, do., £15 15*s.*

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital contains 230 beds, 50 beds being specially reserved for patients suffering from fever and other contagious diseases. Two Clinical Lectures will be delivered in each week, in addition to the daily bedside instruction. A special course of lectures on Fever will be given. A certificate of attendance upon this course, to meet the requirements of the King and Queen's College of Physicians, may be obtained. A ward has been assigned for the treatment of Ophthalmic Diseases. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the dispensary held on Wednesdays and Fridays during the session. Lectures on Clinical Gynæcology will be delivered on Wednesdays. "Leonard Prizes" (Clinical): Prizes of the value of £30 will be given at the end of the winter session, in accordance with the directions contained in the will of the late Mark Leonard, Esq. Certificates of attendance upon this hospital are recognised by the Royal University and all the licensing bodies in the United Kingdom.

Fees.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.*

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic diseases.

There will be a distinct course of Lectures and Clinical Instruction in Fevers. Operations are performed on Monday and Wednesday mornings, except in cases of emergency. A course of Practical Instruction in Ophthalmic Surgery will be given. Fee for the certificate, £3 3s.

A Resident Surgeon is appointed every alternate year, receives a salary, and holds office for two years. Eight Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students, as formerly, but also to those who are qualified in Medicine or Surgery. Dressers are selected from among the best qualified of the pupils, without the payment of additional fee.

COOMBE LYING-IN HOSPITAL, AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN.—The hospital contains 65 beds, and has also a large extern maternity attached. Nearly 3000 confinements are attended annually by the pupils of the hospital. A special dispensary for diseases peculiar to women is held daily, and clinical instruction given. The certificates of the hospital are recognised by all licensing bodies, and its diploma is accepted by the Local Government Board, &c. Further particulars can be learned from the Master at the hospital.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for Diseases peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in midwifery, and

Digitized by Google

lectures on these subjects are delivered regularly throughout the session. Accommodation is provided for a limited number of intern pupils.

MEDICAL TEACHERS.

Dr. ALTSCHUL has made Stuttering, Lisping, Falsetto, recent or of long standing, due to Nervousness, &c., irrespective of age or sex (without any mechanical appliances), his special, life-long study. The voice developed and strengthened.—9, Old Bond-street, W.; and at Brighton and Hastings.

Messrs. BAILLY and COATES prepare candidates for Matriculation, Apothecaries' Hall, College of Preceptors, and all other English, Scotch, and Irish Medical Preliminary Examinations.—30-32 Ludgate-hill, E.C.

Mr. J. BECKTON, C.M., prepares candidates for the London Matriculation, Medical and Law Preliminary, University, Local, and other Examinations. Boarders received.—41, Torrington-square, W.C.

Messrs. BOSWORTH and STERN prepare for Preliminary Medical, First B.Sc., &c.—Kenmore, Putney, S.W.

Mr. L. BRYAN, M.A. Cantab., continues for the thirteenth year his most successful preparation of resident and non-resident students for Matriculation and the Medical Preliminaries. Students entering at any of the hospitals are taken as boarders and receive careful supervision, every home comfort, and assistance in their professional studies.—140, Gower-street, W.C.

Mr. H. CRASSWELLER, B.A., prepares candidates for Medical and Law Preliminaries and Matriculation.—12, Aberdeen-park-road, Highbury, N.

Mr. A. H. DAWES, 1st B.A. Lond., gives lessons privately, in class or by post, in preparation for the London Matriculation and Medical Preliminary Examinations.—31, Southampton-street, Strand, W.C.

Mr. H. N. DIXON gives a thorough and high-class education to Deaf Children based upon the Oral method.—25, St. Paul's-road, Northampton.

Mr. JOHN EVANS, M.A., prepares candidates for all Examinations.—Queen's-park, Oswestry.

Mr. J. GIBSON, M.A., prepares candidates for the London Matriculation, and Preliminary Medical and Legal Examinations.—Quernmore, Bromley, Kent.

Mr. THOMAS LYLE, M.A., F.R.Hist.S., of the London and Dublin Universities, prepares gentlemen, resident and non-resident, for the various Preliminary Arts Examinations and Matriculation at the London University.—Grove House, Shacklewell-lane, London, E.

Mr. MAINWARING, B.A., prepares candidates for all Preliminary Examinations.—115, Edith-road, West Kensington.

Mr. A. ORMOND prepares candidates for Preliminary Medical Examinations.—24, St. Mary Abbott's Terrace, Kensington.

Mr. PIESSE prepares candidates in Materia Medica, Botany, Pharmacy, and Chemical Physics.—Savoy House, 115, Strand, W.C.

Mr. W. VAN PRAAGH has made the cure of all Defects of Speech, both acquired and congenital, his special study.—11, Fitzroy-square, W.

Mr. J. W. SAUNDERS, A.P.S., G.S.T., prepares gentlemen for Examination in Anatomy, Physiology, Botany, Chemistry, Materia Medica, Pharmacy, &c.—6, Rochester-square (late Camden-road), N.W.

Mr. H. SERGEANT, B.A. Lond., holds special classes for London University Matriculation, the Preliminary Medical Examinations, &c.—8, High-street, Camden-town, N.W.

Mr. V. BUTLER SMITH assists pupils in reading up for the London Matriculation, and Legal, Medical, and Pharmaceutical Examinations.—Polytechnic, Regent-street, W.

Mr. H. WAITE prepares pupils for Matriculation, Preliminary Scientific, and the Examinations for Medical Registration of all the licensing bodies.—342, Strand, W.C.

Mr. F. A. WHITE, B.A., prepares candidates for Matriculation and Medical and Legal Preliminary Examinations.—67, Richmond-road, Bayswater, W.

Mr. H. W. WHITE educates Deaf and Dumb Children of the higher classes on the Pure Oral system.—115, Holland-road, Kensington.

Mr. MAURICE WILLIAMS prepares candidates for Examination in Theoretical and Practical Chemistry, Materia Medica, &c.—The City School of Chemistry, 27, Chancery-lane, W.C.

Mr. J. WOODLAND, F.L.S., F.C.S., holds classes and demonstrations in Practical and Theoretical Chemistry, Chemical Physics, Materia Medica, and Pharmacy; in the Botanical classes specimens are supplied to each student, and all apparatus is found for the Practical Chemistry course. These classes are held for candidates for the Primary L.R.C.P., L.S.A., and the M.B. degree of the different Universities, at the Central School of Chemistry.—173, Marylebone-road, N.W.

Annotations.

"Ne quid nimis."

TREATMENT OF SCARLET FEVER.

IT would be interesting if a census were to be taken with a view to ascertain what treatment of scarlet fever was most in vogue amongst practitioners of to-day. We suspect that not an inconsiderable portion of this vote would fall to the lot of expectancy, by which must be understood the absence of any attempt to arrest the course of the malady, combined with great watchfulness of the symptoms and the treatment of the most dangerous of these morbid phenomena. The present epidemic is for the most part of a mild nature, but considerable attention has to be given to the throat, which seems to suffer in a marked degree, the glandular swelling being correspondingly marked. Hence it will be found that gargles of all kinds, and especially those of an antiseptic nature, are freely used, together with compresses of various degrees of heat and moisture applied to the neck. Most practitioners, even those of the most expectant schools, employ topical applications to the throat and nose. Many articles are used to relieve the thirst and sensation of dryness, but nothing is more effective than ice and a little raspberry vinegar. It is important to keep the nostrils and nasal passages sweet and clean. For cerebral symptoms, nothing is better than the application of cold, either in the mild form of lint soaked in iced water and applied to the shaven head, or in the more effective capilline tubes, with irrigation. Compression of the carotid arteries and bleeding are seldom practised nowadays, either in scarlet or any other fever. Aconite in minute doses, frequently repeated, is still the favourite drug of many practitioners, but its employment needs the exercise of clinical discretion, especially in children. Actual bathing in cool or tepid water is practised by but few physicians, though the number of practitioners who recommend the use of cold or tepid sponging, the patient lying in bed on a mackintosh, appears to be largely on the increase. Most of the alleged specific and curative agents have long since lapsed into discredit. Belladonna finds but few adherents, and carbonate of ammonia almost none. Considerable difference of opinion exists on the merits of inunction with fat, cold cream, and the like, two of the most recent authors on the diseases of children taking opposite views, Dr. Goodhart advocating and Dr. Angel Money opposing the universal inunction, though the latter sees no objection to relieving the tension of the palms and soles by the application of geoline or vaseline scented with eucalyptol.

ACETONURIA IN INFANCY.

THE researches of von Jaksch and of Penzoldt, and many others, have shown that the occurrence of acetonuria is not the special appanage of grave diabetic accidents (*vide* THE LANCET, vol. ii. 1885, p. 392), but may occur in a great variety of diseases, including fevers, carcinoma, and insanity. There seem also some grounds for believing that even the healthy organism may not be altogether free from the presence of some of this said acetone which is unquestionably a deleterious body, though it is possible that minute doses of it, like minute doses of many other poisons, are borne by the economy with impunity. Baginsky has given much attention to the occurrence of acetonuria in infant life, and from his researches it would appear that amongst children a physiological acetonuria of slight degree and inconstant nature does exist. Pathological acetonuria is common amongst children suffering from febrile disorders, and the presence of acetone in the urine appears to be related directly to the intensity of the febrile process, since a slow

Digitized by Google

diminution in the amount of acetone in the urine has been observed in pneumonia from its commencement to its termination. The researches of Baginsky, whilst admitting the existence in a slight degree of acetonuria during the normal life of infants, prove, so far as they go, that acetonuria is specially to be associated with the febrile state, and, in fact, that it increases with an increase in the fever. It has been proved, also, that a fleshy diet increases acetonuria, whilst the ingestion of non-nitrogenous food is not followed by acetonuria. Since acetonuria of a very intense degree may be discovered in the course of convulsive diseases in infancy, it is obvious that many mechanisms are capable of setting up the conditions on which the presence of acetone in the urine depends. It seems clear, however, that neither asphyxia induced by, nor the administration of choral for, the convulsive seizures is an efficient explanation; nor are there good grounds for believing that acetone can be regarded as a common cause of convulsions, for these spasmodic affections may be unattended with acetonuria, and, further, acetonæmia is not usually the cause of tonic or clonic spasms, as the experiments of Baginsky showed. We neither know for certain the place at which acetone originates, the materials out of which it is constructed, the precise effects on different tissues, nor its ultimate fate in the metabolic system. Conjectures have been made that it originates from hydro-carbons of digestion; but Baginsky has discovered acetonuria in a dog fed wholly on animal food, whilst acetone disappeared from the urine when the dog was fed exclusively on hydro-carbonaceous material. It appears probable that nitrogenous material is the source of this chemical body. Baginsky has found a considerable amount of acetone in the urine of a child aged four years, who had swallowed some dilute nitric acid. Grave symptoms, with loss of consciousness, delirium, grinding of the teeth, and small pulse, were observed as the effect of the intoxication; the urine was albuminous also. The acetonuria could not be ascribed to the fever, for the temperature did not go beyond 38·2° C., but there was considerable disintegration of nitrogenous material. Although Jaksch admitted that acetone is formed during the lactic acid fermentation, yet a chemical examination of the contents of the stomach drawn off by washing, and of the intestines as discharged per anum, failed to detect appreciable quantities of acetone; the source of the acetone can therefore hardly be traced to any functional disturbance of the digestive organs.

THE ILFRACOMBE DISASTER.

THE sad yachting accident at Ilfracombe, by which it is feared that fourteen or fifteen lives have been lost, on a smooth sea in a summer afternoon, and within easy sight of land, is in danger of being dismissed a little too hastily. It happened on Friday, between 3 and 4 P.M.; and on the evening of the next day the coroner closed the investigation, and the jury returned a verdict of "Accidental death." When such a dismal disaster as this occurs, the one redeeming use to be made of it is the extraction of such lessons as will tend to prevent the recurrence of another. A little less sail, a little more ballast, a little more discipline in the management of the movements of the passengers, a little more preparation for an ordinary squall and its consequences, a greater number of seamen in a crew,—one or more of these or other such precautions might probably make all the difference and avert catastrophes that not only bring the greatest and most irreparable distress to families, but unnecessary discredit on boating pleasures, and on the admirable and noble class of boatmen who are so unselfish and so efficient. We regret that the accident has not been turned to better account, and that the jury have not come to a more definite conclusion. One lesson of the accident is the value of swimming. One of the survivors, who owes her life to it, is a little girl of nine years, who, it is said, had only had one lesson. It is gratifying to report how prompt and hearty were the efforts of the profession of the town, assisted by several visitors, to restore those brought to shore.

INFLUENCE OF TEMPERATURE ON MORTALITY RATES.

EVERY season of the year as certainly brings its crop of one or another disease as of some special form of vegetation, and those upon whom devolves the duty of providing hospital accommodation for infectious maladies know at what period arrangements must be made for cases of scarlet fever and enteric fever, and during which months it may be anticipated that typhus and small-pox will have the best opportunities for their development. The seasonal prevalence of epidemic disease has been long understood, and the records of the Registrar-General and the writings of Dr. G. B. Longstaff afford ample material for learning the months of the year during which the maximum number of cases of each affection may be anticipated. But, with few exceptions, it cannot be argued that a hot season will produce a greater prevalence of any one disease than a period during which the temperature is lower. Scarlet fever, which is at its minimum from January to May, and attains its maximum in October and November, does not appear to have this maximum accentuated by a specially high temperature of the atmosphere. The circumstances which affect its prevalence are evidently not limited to climatic conditions alone, but are more especially those which have led to the accumulation of susceptible persons in a community. Diphtheria, however, which differs from scarlet fever in the particular that it does not appear to protect the infected individual against subsequent attacks, and therefore cannot by its presence or absence affect the amount of susceptibility of the population, is also liable to periodic prevalence, and attains its maximum influence on the death-rate a little later than scarlet fever, although its distribution during the year is more equal than that of the latter disease. The lowness of temperature of the winter months undoubtedly influences the mortality from affections such as measles and whooping-cough, which frequently kill by pulmonary complication. But their prevalence is also seasonal, and the greater number of deaths from the former diseases actually occurs during May and June, when the temperature is much above that of the average of the winter months. Of the acute infectious diseases, the effect of temperature is, perhaps, most marked in its effect upon the prevalence of small-pox, high temperature appearing to be inimical to its diffusion. The class of affections beyond all others which are developed in periods of high temperature are bowel disorders, and especially infantile diarrhœa, which regularly claims its victims after the first few weeks of warm weather, and which develops an especially destructive power, which is directly dependent upon the height of the temperature. The researches of Dr. William Johnstone of Leicester, which are being continued by his successor in that borough, have raised a strong probability that this disease is of bacterial origin, and the objections to this theory, based upon the fact that as a rule infants alone lose their lives from this cause, has been answered by Dr. Johnstone, who has shown that older members of the invaded household are frequently attacked by similar symptoms, which, however, affect the stronger person less severely. The hot season which England has recently experienced has not been without its effect on infantile mortality from this cause, and London has suffered at the rate of fully 50 per cent. more than the average of the past ten years. A full understanding of all the conditions which tend to produce this terrible mortality is sadly needed in the interest of

Digitized by Google

humanity; but work of this character is arduous and intricate, and will require the patient observation of skilled investigators for years before the conditions of life can be accurately appreciated which are responsible for its occurrence.

THE NEW LABORATORY AT KING'S COLLEGE, LONDON.

EVERY effort is being made for the completion of the new Bacteriological Laboratory by October 1st. The laboratory will consist of three rooms. The principal room was one of the largest lecture rooms in the College, and will afford ample accommodation for the practical courses in November and April, and for those who wish to undertake original investigations. Two new rooms are being built for the Professor and his assistants. Each student will be accommodated in a section of the laboratory, where he can work independently and undisturbed. The plan of study followed by each student will depend on the object he may have in view. He may work entirely independently for a month, or for a longer time by arrangement. He may join the laboratory for private study under the supervision of the Professor. He may attend the laboratory when lectures with practical instruction are daily given by the Professor. For this purpose practical courses will be held in November and April. The lectures during these months will be daily from 10 to 11 A.M., and will be illustrated with diagrams and typical preparations, and followed by practical work. The laboratory will be open the first week in October, and closed at the end of June. The hours of attendance will be daily from 10 A.M. till 4 P.M., except on Saturday, when the laboratory will close at 1 P.M. For further particulars applications should be made to Professor Crookshank.

ENDARTERITIS AND SPINAL SOFTENING.

THE pathology of cerebral and spinal softening is still often obscure, especially of the latter. Many cases of so-called transverse myelitis have nothing inflammatory in their nature; some are attributed, and with reason, to anæmic necrosis. The occurrence of such a case in Liebermeister's clinic has afforded Professor Nauwerck the opportunity of making an examination in a comparatively early stage of the disease. (*Beitr. zur Path. Anat. u. Phys.*, Bd. ii., Jena, 1887.) The patient was attacked with paraplegia in October, and died in December, 1885, the fatal issue being hastened by an extensive scald, brought about by her being placed in an over-heated bath. The cord in the region of the fifth to the eighth dorsal nerves appeared soft, moist, swollen, and white, the grey matter being very indistinct. Scrapings of the cut surface yielded spheres of fatty granules and free oil globules. On microscopical examination, in the cervical region there was degeneration of the columns of Goll and the cerebellar tracts. The degeneration involved larger areas as the mid-dorsal region was approached, so that at the level of the sixth dorsal nerve no demarcation was visible between the white and grey substance, the whole of the section appearing cloudy, studded with yellow and greenish-yellow spots. At the level of the seventh nerve the grey matter was slightly defined, but near the left posterior column, reaching to the posterior commissure and involving the central part of the right column of Goll, was a sharply-defined focus, oval in shape and of a yellow colour, which contained small drops of myelin, compound granule corpuscles, oil globules, and some round cells. Below this point the amount of degeneration gradually dwindled, the pyramidal tracts in the lower dorsal region alone being involved. In the main, the degenerative changes were limited to the white matter, the axis cylinders and medullary sheaths being swollen or broken up into masses of myelin and fat granules. Some medullated fibres in the grey substance were similarly changed, but the ganglion cells appeared unaffected. In all parts the destruction of nerve fibres was accompanied by a slight degree of sclerosis from proliferation of the neuroglia. The small focus of softening, which formed a cavity with curdy contents, at the level of the seventh nerve, was the most advanced in degeneration, the neuroglia as well as the nerve elements being destroyed. But in no part was there any evidence of inflammatory change. The small arterioles in the vicinity of the focus of softening presented thickening and hyaline changes in their walls; some of the vessels in the mid-dorsal region being quite occluded by pale thrombi, others showing marked proliferation of endothelium. Similar arteritic changes were traced throughout the dorsal region and into the cervical and lumbar regions. This case seems, then, to link spinal softening with cerebral, placing it among ischæmic processes rather than inflammatory. Nauwerck says this case is the first in which arteriosclerosis has been shown to be the cause of spinal softening; and the cause of the arterial lesion in so young a subject (twenty-four years) is presumably to be found in a severe attack of typhoid fever, which the patient had three years before.

THE PROGRESS OF CHOLERA IN EUROPE.

DURING the past week cholera has continued in Malta, but with some tendency to diminution in the numbers attacked. In the seven days ending August 29th, there were 38 fresh attacks and 26 deaths, the total number of deaths since the commencement of the outbreak at the beginning of August amounting to about 121. In Sicily the disease is principally centred in the provinces of Catania, Palermo, and Messina, the fatal attacks in the seven days ending August 29th having been 48, 47, and 2 respectively. But accounts of the disease, without mention of the number of cases and deaths, also come from other localities. On the mainland cholera cases and deaths still occur daily at Naples, and there are indications of at least solitary attacks in the vicinity of the city, as, for example, at Castellamare. Fourteen deaths are also reported from Capo Colonne, just to the south of Cotrone in Calabria. The order relating to the prohibition of rags from Italy into this country has now been issued, and it will remain in force until the end of the year.

THE SPINAL NERVE ROOTS.

DR. E. SIEMERLING has, at the instance of Prof. Westphal, made a careful anatomical examination of the structure of the roots of the spinal nerves, with a view to throwing light upon the paths taken by lesions of peripheral parts secondary to disease of the cord—e.g., tabes. His monograph ("Anatomische Untersuchungen über die Menschlichen Rückenmarkswurzeln," Hirschwald, Berlin, 1887) is illustrated by plates which clearly indicate the point that each nerve root contains a variable number of small and of large nerve fibres, the smallest being only 1·3μ and the largest 23·9μ in calibre. The maximum thickness is smaller in the posterior (viz., between 8·0μ and 21·3μ) than in the anterior roots (13·3μ and 23·9μ). The fibres are largest in the anterior lumbar and three upper sacral roots; next come the anterior cervical, posterior lumbar and sacral (upper line); next the posterior cervical and last two sacral roots. The dorsal roots have about an equal proportion of small and large fibres. In the whole series there is about the same relative proportion of large to small fibres in the posterior (viz., 1:1·2) and anterior (viz., 1:1·1) roots. But except in the dorsal region, the number of large fibres is greater in the anterior roots than in the corresponding posterior, which, except in the lumbar region, contain about an

Digitized by Google

equal number of each variety. The number of large fibres and their thickness correspond to the size of the root, and these fibres are therefore largest and most abundant in the anterior lumbar, cervical, and sacral roots. The fine fibres are for the most part disposed in groups of larger and smaller size between the bundles of large fibres; and the greater the number of small fibres in proportion to the large, so much the larger are the groups in which they are collected. These small fibres are isolated and scattered in the anterior cervical, lumbar, and upper three sacral roots. In the posterior cervical, lumbar, and upper three cervical, as well as in the last two sacral roots, the fine fibres are disposed in small groups. In the dorsal roots they are collected into large bundles. The anterior roots of the cervical and lumbar regions are the first to be fully developed. The mode of research adopted by Dr. Siemerling was to make transverse sections of the nerve roots, to calculate the number of fibres contained in each, and to make careful measurements of them. This was done not only in the adult body, but also in the new-born and the fœtus; so that it must have entailed a great deal of labour, which will, it is to be hoped, be proportionately fruitful.

THE PREVENTION OF SUMMER DIARRHŒA.

WE have on more than one occasion drawn attention to the excellent work which has been done by Dr. Victor C. Vaughan, of the University of Michigan, in regard to the production of the poison tyrotoxicon in milk and cheese, and as to his views that the development of this substance in milk is a frequent cause of choleraic diarrhœa in infants. According to a report recently presented to the State Board of Health of Michigan, the poison has been found not only in milk and cheese, but also in ice-cream and oysters; and pending the publication of the completed document, so much of the report as bears upon the prevention of cholera infantum has been issued for the information of the public. By the poor, as is well known, milk is often not obtained until after it is no longer fresh; it is badly stored until used; and it is on such milk that children are fed. The cleansing of feeding bottles is also less attended to by the poor than by others, and the crusts of decomposing milk which form round the neck of the bottle and in the tube and nipple tend to the rapid decomposition of the contents of the bottle itself. It is also essentially amongst the poor that diarrhœa is so fatal to the infant population. Dr. Vaughan, under these circumstances, lays down certain rules which should especially be borne in mind in the warm months of autumn weather, and which concern the collection and storage of milk. Only the milk of healthy cows should be used, and, to favour healthiness, swill and the refuse of breweries, or fermented food, should not be given to the animals. The pastures should also be free from noxious weeds. Stagnant water, as a drink for milch cows, should be avoided; the animals should not be worried or heated, and their udders should be washed before milking. The milk should be at once cooled down to at least 60° Fahrenheit within an hour; and, in addition to certain usual cautions in methods of delivery, it it laid down that only tin, glass, or porcelain vessels should be used for the storage of milk. It is not known how the poison tyrotoxicon is produced, but it is believed either to be the butyric acid ferment or some ferment which is frequently developed along with the *Bacillus butyricus*, and if milk be inoculated with this and kept at the temperature of the body the poison will appear. The butyric acid ferment often develops in the stomach, and the bacillus grows best in the absence of air. Having regard to these considerations, Dr. Vaughan points out how largely children are allowed to drink milk in the summer months as food or merely to quench thirst, and he believes that when summer diarrhœa occurs, one of the first points to be attended to is to stop the administration of milk in any form. The ferment, he holds, is in the alimentary canal, and to give milk is simply to supply the germ with material for the production of the poison. This no-milk treatment is by no means a new idea, but Dr. Vaughan holds that the main reason for adopting it—namely, the fact that a powerful poison is formed from the putrefaction of milk—has not been understood. He suggests that, under the circumstances referred to, chicken and mutton broths, beef juice, and rice or barley water should take the place of milk.

THE BREATHING SPACES OF OXFORD.

THE recent memorandum by Dr. Thorne Thorne and Mr. Gordon Smith on the overcrowding of houses on area in Oxford, and on the unwillingness of the Local Board to take action with a view of preventing extension of the mischief, has been received with mingled feelings in Oxford. The *Oxford Times* considers that the city has been "somewhat unjustly scandalised"; but it immediately proceeds to indicate how trivial the unjustness must be, by regretting that the inspectors did not deal with what is evidently considered by them as a still greater, indeed "the one actual blot," in Oxford—namely, the "huddling together in mere hovels in narrow passages of hundreds of human beings compelled to live in tenements almost deprived of light and air," and this under sanitary conditions alleged to be as bad as can possibly be. In short, all that can be said for Oxford in this respect is that, in addition to the general crowding together of business houses and courts in the central parts of the city, disgraceful hovels in "unsavoury courts" exist, and that the individual tenements are overcrowded to an extent that is discreditable. The instructions under which the Government inspectors acted seem to have limited them to one point only, but the local press shows how well they might have been extended to other matters also. Almost everyone in the city is taken to task about the Oxford "slums." The Colleges are declared to be great "sinners" who altogether fail to show a good example, and the local authority are accused of not being slow to follow in the retrograde path of the University authorities. In short, it is Oxford as a city and a university town—that is to say, Oxford as a whole—that is to blame. We imagine that this is precisely the contention of those who have recently reported on the city, and it goes for very little, after this admission, to urge in extenuation that people who have to live, eat, and sleep in such crowded spots can, if they have time to take a five minutes' walk, find in the College gardens a large number of "lung spaces."

ODONTALGIA v. NEURALGIA.

THE great difficulty occasionally experienced in diagnosing whether neuralgic pain of the fifth nerve is due to peripheral irritation from disease of the teeth or to some affection of the nerve trunk, made Prof. Victor Horsley's paper on this subject at the Odontological Society of considerable interest, especially to dental surgeons. The principal points of distinction may be summed up under the following heads: 1. Trophic changes, such as muscular wasting in the parts to which the pain is referred, chronic congestion, or alternating dilatation and constriction of the bloodvessels, point to mischief in the trunk of the nerve. 2. Alterations in sensation, anæsthesia or hyperæsthesia of the skin, especially when gently touching the skin causes extreme pain, while firm pressure causes no pain at all, are, he believes, never due to dental irritation. 3. The origin and character of the pain are sometimes useful as a means of diagnosing the two conditions. When the pain begins in the skin or bone, and subsequently is referred to the teeth, the probability is that

Digitized by Google

the lesion is in the nerve trunk; if it is stated to begin in the teeth, it may or may not be due to them. Professor Horsley expressed the view that *constant* pain is in most cases of peripheral origin, whereas intermittent pain is due to trouble nearer the nerve centre; but this is opposed to the experience of most dental surgeons, intermittent pain being a frequent accompaniment of dental disease. Lastly, the existence of "tender spots" along the course of the nerve or its branches is generally an indication of irritation along the whole course of the nerve, but occasionally occurs in cases of peripheral irritation.

PROFESSOR PEL ON ACUTE RHEUMATISM.

IT has been remarked by Professor Pel of Amsterdam that the cases of ague and rheumatic fever which have been admitted into his clinic during the last few years have borne an inverse ratio to one another in point of numbers. Thus, in 1875, there were 10 cases of ague and 22 of rheumatic fever; in 1876, 14 of ague and 9 of rheumatic fever; the number of cases of ague then rose very high, being for the next five years 31, 40, 41, 31, and 23 respectively; while the rheumatism cases were comparatively infrequent, the numbers being 7, 10, 11, 11, and 9. In 1882, the ague cases numbered 9, and the rheumatism cases 10. The latter then again began to rise, being for the next three years 42, 43, and 44; while the ague cases numbered only 12, 10, and 14. The influence of climate on rheumatism has been touched upon by various authors, one of the best known papers on the subject being that of Dr. Gabbett, which was published in THE LANCET of Oct. 20th and 27th, 1883. Edlefsen also communicated an important paper to the Wiesbaden Congress in 1885, showing that the mortality from acute rheumatism bears some relation to the rainfall. Professor Pel finds that rheumatism often attacks a number of persons on the same day, and on comparing these "rheumatism days," as he calls them, with meteorological records, he has observed that they are usually days on which little or no rain has fallen. They do not occur during long rainy periods, and the temperature only seems to have any effect when its fluctuations are considerable. He has also remarked that from five to ten days before a "rheumatism day" a considerable downfall of rain has usually occurred. He has a strong belief in the specific nature of rheumatic fever, and in support of this points to its resemblance to other specific fevers in the manner of its invasion, in its liability to affect serous membranes, in its epidemic character, and in the special characters marking particular epidemics. He also narrates the case of a woman just recovered from typhoid fever and double pneumonia, who was seized with rheumatic fever on the same day that five other patients suffered from relapses. She occupied a bed between two patients with acute rheumatism. It only wants, he thinks, the discovery of the specific micro-organic cause of the disease in the inflamed serous membranes to render the present presumption of its specific origin a certainty.

URETERO-GENITAL FISTULÆ.

DR. C. D. JOSEPHSON describes in the reports of the Sabbatsberg Hospital, Stockholm, a case of uretero-uterine fistula, in which he performed nephrectomy with satisfactory results. The patient was twenty-four years of age, and the confinement was her third. Forceps were employed. During the puerperal period she had fever, and there was some effusion into the pelvis. She also suffered from incontinence of urine, while at the same time she was able to micturate in a normal manner. The left ureter was found to open in the cervix uteri. Dr. Josephson discusses this case, and twelve similar cases which he has found in medical literature. He suggests the possibility of a sudden rupture during labour either when the ureter has been fixed to the cervix uteri by a previous inflammation, or when the tissues have become friable or incipient gangrene has occurred owing to the pressure of the child's head. The fistula may, however, be established during the puerperal period, owing to the formation of an abscess or to a gangrenous condition of the tissues. The pathognomonic signs of the existence of this rare accident are a constant dribbling of urine, while at the same time it is passed in an ordinary manner, and especially the possibility of filling the bladder with a coloured liquid without producing any colouration in that which runs away involuntarily. The treatment consists either in the performance of nephrectomy or in the occlusion of the vagina. Uretero-vaginal fistulæ, of which twenty-three cases are cited, are divided into four groups. 1. Simple fistulæ (uncomplicated with vesico-vaginal fistulæ) caused by a labour under conditions similar to those which give rise to uretero-uterine fistulæ. 2. Those complicated with vesico-vaginal fistula. 3. Those caused by operative procedures, such as the opening of an abscess, the excision of the cervix, or the total extirpation of the uterus. 4. Congenital fistulæ. The symptoms are similar to those of uretero-uterine fistula. The treatment consists in a complicated plastic operation as practised by Simon, Bandl, Schede, and others. When this operation is impracticable, nephrectomy or occlusion of the vagina should be performed. Dr. Josephson suggests that in these cases it might be possible to attempt the formation of an artificial urethra, consisting of a fistulous canal between the interior of the bladder and the urethra above the uretero-vaginal fistula.

INDUCTION OF PREMATURE LABOUR IN THE BERLIN CLINIC.

FROM a graduation dissertation on artificial induction of premature labour by Dr. Johannes Panienski, founded on the practice of the University Clinic for Women in Berlin, we learn that in the ten years 1877-1887 this operation was performed twenty times for contracted pelvis. In 10 of these cases there was a flat rickety pelvis, with a conjugate diameter of from 8 to 7 centim.; in one case, indeed, it only measured 6·7 centim.; and here, notwithstanding that the transverse diameter of the fœtal cranium was 8·5 centim., both mother and child did well. As induction of premature labour is undertaken in cases of contracted pelvis chiefly with the view of saving the child, it is noticeable that only 3 of these 10 children lived, but that out of 12 children previously born of the same women only one had lived. Labour was induced twice in cases of flat, non-rickety pelvis with conjugate diameters of 9½ and 8½ centim. respectively; in the first case, because the 5 previous children had all presented transversely, 4 of them being still born. In both cases of induced labour the children lived. In 2 cases there was a generally contracted pelvis, with a conjugate diameter of 7¼ centim. In 6 cases there was an oblique contracted pelvis, with a conjugate diameter of 8 centim., 5 of these being in the same woman. Of the 20 cases, 2 were primiparæ; the 18 others resulted in the deaths of 9 children—i.e., 50 per cent.; whereas of the 26 children of which the same women had been previously delivered at term, 23, or 88 per cent., were stillborn, so that we may consider that operative interference saved 38 per cent., reckoning those as living which were alive when the mother left the clinic on the eleventh or fifteenth day. The induction of labour was carried out under the strictest antiseptic precautions. Seventeen of the 20 women passed through the puerperal period in a perfectly normal manner; one died from air embolism; one showed signs of septic mischief, and one suffered from slight perimetritis—both these, however, completely recovered. The method employed was that of Krause, with this modification—viz., that a bougie

Digitized by Google

was used instead of a catheter. In one case an attempt was made to bring about the labour by a subcutaneous injection of pilocarpine, but this proved useless, even though hot vaginal douches were subsequently administered; so recourse was had to the bougie. The action of the bougie is prompt and certain, though not alike in all cases. The time from the introduction of the bougie to the birth of the child varied from 6 hours to 16 days, the average time being 79 hours. The first pains were felt in from 1½ hours to 5 days after the operation, the average time being 24 hours. The duration of the pregnancy varied from 32 to 36 weeks. With regard to diseased conditions of other organs, labour was induced 11 times, 4 times for kidney affections depending on pregnancy, 6 times for chronic nephritis, and once in a case where there was an uncompensated cardiac affection, which gave rise to very serious symptoms—viz., almost complete blindness from albuminuric retinitis; a considerable amount of ascites with hydrothorax and enormous œdematous labia, together with paroxysms of dyspnœa. In three of the kidney cases there was eclampsia. The results were encouraging, as all 11 women recovered. The bougie was employed 9 times, puncture of the membranes twice. Pilocarpine was first tried on the case with œdema; it produced sweating, but entirely failed in inducing pains.

HÆMOPTYSIS TREATED BY INJECTIONS OF ERGOTIN.

M. GUELLIOT publishes in a Rheims medical journal some notes of a case in which he injected ergotin into the lung. The patient had been suffering for two years from daily hæmoptyses, which had been treated in various ways, but unsuccessfully. Subcrepitant rales could be heard in considerable numbers three fingers' breadth above the liver in front. The man had had pleurisy twenty-two years previously. His general appearance was good, and no tubercle bacilli could be detected in the sputum. M. Guelliot determined to try the effect of injections of ergotin in glycerine into the affected region, employing the strictest antiseptic precautions. After a few drops of the solution had been injected the patient brought up sputum of a distinctly sweetish taste, showing that the injected liquid had been absorbed. The injections were continued, the quantity of liquid introduced being gradually increased. The hæmoptysis began to diminish. The treatment had, after a time, to be stopped, as signs of broncho-pneumonia developed. Ultimately the patient died. The base of the right lung was found to be in a state of grey hepatisation, and there were pleuritic adhesions round all the lower half; also some tubercles at the apex. The interesting point about the case is the fact that after fifteen or twenty ergotin injections the hæmoptysis diminished in a remarkable degree.

SURGICAL SCARLET FEVER.

HOFFA (Volkmann's Sammlung, 292, abstract in *Centralb. f. Bacteriol.*, Bd. ii., No. 8) says that cases of so-called "surgical scarlet fever" fall under one of four categories. They may be—1st. Cases of congestive erythema, clearly due to vaso-motor disturbance. 2nd. Toxic erythema, like the erythematous rashes due to drugs, and depending upon absorption of products of tissue destruction. 3rd. Septic or pyæmic rashes, as the outcome of general septic infection, and probably due to capillary embolism of micro-organisms. 4th. True scarlatinal infection, as verified by one or other of the concomitant symptoms, angina, swelling of submaxillary glands, nephritis, and desquamation. To describe the scarlet fever as "surgical" the infection must occur at the wound, and the exanthem spread therefrom over the body. Such cases, Hoffa states, are rare; and he details the only two which have come under his personal observation. One was a case under treatment for rupture of the urethra with extravasation of urine, which was doing well, until on the ninth day a scarlatinal rash appeared, and spread from the wound over the abdomen and buttocks. It was accompanied by sore throat, and disappeared in a week, but the patient succumbed from cardiac degeneration and acute nephritis. The other case was one of fracture of both femora, and a wound extending into the rectum; was attacked four days after the former case, and recovered with marked desquamation. Streptococci (like the S. pyogenes and the erysipelas coccus) were cultivated from the skin and blood of the first case; but inoculation experiments gave no result.

HYDROCHLORATE OF APOMORPHINE.

THIS useful salt has been extensively tried by Dr. Stocquart of Brussels as a remedy for certain kinds of cough, and he speaks highly of its value. The kind of cough in which it has proved most successful is a distressing and frequent hacking unattended with expectoration, or with exceedingly difficult expectoration, and the improvement of the patient's condition is usually effected in a few days. The drug is as a rule well borne, although a few individuals manifest a special susceptibility to its action, and rarely nausea, colic, and diarrhœa result from its employment. The dose is a minute one, only three or four milligrammes of this alkaloid being given in water in the twenty-four hours; and as the solution rapidly alters by keeping, it is advised to prevent its decomposition by the addition of a few drops of hydrochloric acid, which does not interfere with the therapeutic effects.

URÆMIC HEMIPLEGIA.

GENUINE hemiplegia, or loss of power of the will to move the limbs on one side of the body, does occur in uræmia, but only rarely. As a rule, hemiplegia associated with uræmia is due to a gross vascular lesion. But cases like one described by Dr. Wiglesworth in the July number of the *Liverpool Medico-Chirurgical Journal* prove the dependence of hemiplegia during uræmia on some other cause than a coarse lesion. At the same time, we are not satisfied with the explanation of MM. Chantemesse and Raymond, who, with Dr. Wiglesworth, consider that a serous effusion due to Bright's disease may compress the cerebral arterioles, already weakened by degenerative changes, and so cause paralysis, for it is possible that the same local agency which causes clonic spasms may, if acting in stronger force, cause paralysis; we mean that the same poison may directly cause local loss of function, without the mechanism of a serous effusion having any necessary action in the causation.

GASTRIC ATROPHY AND PERNICIOUS ANÆMIA.

IT may be remembered that to Dr. Fenwick we owe the discovery that certain cases of progressive anæmia depend upon, or at any rate are associated with, atrophy of the gastric mucous membrane. Since then other writers upon pernicious anæmia have described the same lesion in the stomach—one such case recorded by Drs. Henry and Osler being contributed last year to the *International Journal of Medical Science*. In that case there was complete absence of the peptic glands, and gastric digestion was wholly in abeyance. The subject came up for discussion at the recent meeting of the Association of American Physicians (*Boston Medical and Surgical Journal*, No. 26). Dr. Kinnicutt of New York related two cases, in which the typical symptoms of pernicious anæmia were well marked. In each case the only organ found to be affected was the stomach. Its lining membrane was smooth, and microscopic examination showed a great deficiency of the gastric tubules, which

Digitized by Google

were either wholly wanting or else existing only in their more superficial portions. Dr. Delafield regarded the lesion of the stomach as secondary, and pointed out that in many other diseases leading to starvation the symptoms of pernicious anæmia are not developed. Both Dr. Henry and Dr. Osler, who also spoke, held that there is a group of cases, clinically indistinguishable from other cases, of pernicious anæmia, in which gastric atrophy is the primary and essential lesion.

INTUBATION OF THE LARYNX.

IN the course of a paper upon Intubation of the Larynx (*Berl. Klin. Wochensch*, No. 32), Dr. Caillé of New York states that the operation has been performed in 429 cases, with 114 recoveries, or about 26 per cent. The majority of these cases were diphtheria, and more than half were children of three years old and under. It is only fair to state that with improvements in instruments better results have been obtained by O'Dwyer than in his earlier cases, so that as an operation it can hardly as yet be compared with tracheotomy. The advantages of intubation are stated by Dr. Caillé to be—1. That it obviates the necessity of administering an anæsthetic, and thus can promptly relieve dyspnœa. 2. There is no such prolonged after-treatment such as tracheotomy needs. 3. No wound is inflicted as a rule, and therefore no path laid open for infection. 4. The consent of parents to the operation is easily obtained. Dr. Caillé looks to far better results being obtained in the future than hitherto, and urges that especial care should be taken to prevent pneumonia from entrance of foreign matter (*Schluck-pneumonie*), and to this end the tube must be such as not to hinder deglutition. The paper enters into full details of the procedure and the accidents that may arise.

DR. MAX ON RHUS AROMATICUS IN ENURESIS.

DR. MAX, physician to the Children's Infirmary, Brussels, has recently made trial of a remedy recommended by Dr. Ellis, in his work on the Diseases of Children, for incontinence of urine. After referring to the various causes and the different specific forms of treatment of this affection, he remarks that he has never seen the remedy referred to—viz., rhus aromaticus—recommended, except in Dr. Ellis's book, and that he experienced some difficulty in obtaining it, which he ultimately, however, succeeded in doing from the New York Botanic Garden. A tincture was prepared by macerating 200 grammes of the bark in 1000 grammes of spirit at 80° C. This was prescribed in several cases in quantities of from twenty to fifty drops per diem, taken in three doses—i.e., about seven to seventeen drops three times a day. The results were in the majority of cases most satisfactory. In no case was any untoward effect produced.

HEMIPLEGIA IN CHILDREN.

THE chief cause of hemiplegia in children is believed to be embolism, according to the clinical lecture given by Dr. Abercrombie at the Hospital for Sick Children, and published in a medical contemporary. His arguments are not altogether unassailable, and consist chiefly in the observations made in the post-mortem room, that the lesions of atrophy and sclerosis of the brain are mainly confined to that area which happens to be "motor" in function and mainly supplied by the middle cerebral arteries, which are, all will admit, more frequently the seat of embolism than other cerebral arteries. Whilst admitting the general truth of the statement that the "motor" areas are more commonly the seat of sclerosis than other parts of the brain, we cannot subscribe to the statement made by Dr. Abercrombie "that the sclerotic changes are not found to any great extent elsewhere in the brain than in the motor area." He carefully, however, proceeds to say that the sclerosis is not necessarily limited to the motor area; but where not so limited, it is generally found in adjoining convolutions, and here comes an assumption "as if it had spread there." We have nevertheless seen sclerosis freely scattered about, just as might fairly be expected on the hæmorrhagic theory of its origin, or, we may remark, on the theory of arterial sclerosis due to syphilis, which cause is indeed allowed by the author to be operative in a certain proportion of cases. The view which goes by the name of Strümpell's hypothesis does not appear to find much favour in this country.

"LUPUS" OF THE VULVA.

IN the August number of the *American Journal of Obstetrics* Dr. Grace Peckham contributes a case to this vexed question, together with a discussion of the whole subject, and an analytical table of forty-eight collected cases. The paper is illustrated by several reproductions of Huguier's drawings, and by a coloured picture of the author's case. The paper leaves the subject much where it was. Microscopical examination seems to be capable of little more than the exclusion of epithelioma, carcinoma, and sarcoma, and to be practically incapable of differentiating between "lupus" and syphilis, around which question the controversy centres. We are surprised that the author, in a paper published in August, 1887, should make no mention of a series of highly important papers by Dr. Matthews Duncan on this subject, read before the Obstetrical Society of London on May 6th, October 7th, and December 2nd, 1885, published in the Transactions of the Society for the year 1885, and reported in abstract at the time not only in THE LANCET, but in the *American Journal of Obstetrics*. Without analysis and criticism of these the paper misses much of its value. The question in most of these cases is—"lupus" or syphilis?

ARSENIC AND MUMMIFICATION.

PROFESSOR ZAALJER, of Leyden, has recently published a number of observations he has made on the bodies of persons who have been poisoned by arsenic. He finds that the degree of putrefaction of bodies containing arsenic is chiefly determined by the state of the temperature of the air before they were buried. In the grave the putrefactive process progresses at various rates, being sometimes slow and sometimes rapid. Having examined a large number of cases, he comes to the conclusion that the arsenic which had been administered had exercised no effect whatever on the rate of decomposition, or on the mummification so that the so-called arsenical mummification has really no existence whatever—at all events, in cases where poisonous doses of arsenic have been taken. He asserts, therefore, that mummification is absolutely useless as medico-legal evidence of poisoning.

A LARGE NASAL CALCULUS.

DR. NOLTE reports, in the *Allgemeine Medicinische Central Zeitung*, a case of nasal calculus occurring in a woman of forty. The patient came to him complaining of a sore in the mouth accompanied by considerable fetor. On examination, at the centre of the junction of the hard and soft palates, there was found a small round ulcer with eroded edges, in the middle of which a rough, somewhat movable object was felt. The hardness of the body and the note on striking it suggested a nasal calculus, which, on account of its heaviness and its rough surface, had by degrees bored through the palate. For two years the patient had perceived a peculiar and not easily described feeling in the nose. To remove the stone, Dr. Nolte made a longitudinal incision, and, after enlarging the opening, extracted a neuriform nasal calculus of the size of a pigeon's egg, with

Digitized by Google

several large and small processes. The fetor from the mouth soon disappeared, and the patient was well in eight days. The stone was analysed by Herr Ekarius, and found to contain the following substances: phosphate of lime, carbonate of lime, phosphate of ammonia and magnesia, iron, potash, and traces of soda, also indurated nasal mucus.

THE HEALTH OF THE CROWN PRINCE.

THE Crown Prince of Germany has, we understand, derived great benefit from his stay in the Highlands. The disposition to attacks of sudden and rather severe congestion of the mucous membrane, which has been a feature of the malady throughout, is less marked, and the catarrhal attacks much less severe. Vocal fatigue is also much less pronounced, and the general health is all that could be desired. His Imperial Highness has slightly prolonged his stay in London in order to avoid crossing the sea in the tempestuous weather of the last day or two, as Dr. Morell Mackenzie considers that the infirmity which even Princes on Royal yachts cannot escape might have an injurious effect on the throat. Mr. Mark Hovell will accompany his Imperial Highness to the Southern Tyrol.

SCARLET FEVER IN LONDON.

THE demand for hospital accommodation for cases of scarlet fever in London is still increasing, as many as 132 patients suffering from this malady having been admitted into the hospitals of the Metropolitan Asylums Board during last week. Nevertheless, the mortality from this disease is much below the average of the last ten years, the number of deaths registered in the thirty-third week of the year being but 23, as compared with an average of 33·9. Some proportion of this demand is doubtless due to the increasing confidence which is felt by all classes in the treatment of patients in the hospitals of the managers; but this will not entirely explain the large number of admissions to hospital, and the fact remains that a widely spread epidemic of mild scarlet fever exists in all parts of the metropolis. The question has been raised in the daily press as to whether this may be due to an infective milk supply. The distribution of the cases appears to negative this suggestion, although it is possible that earlier cases due to this cause might soon be masked by the rapid development of the disease.

IT is announced from Hamburg that a severe outbreak of trichinosis has just occurred there. In one house alone nine persons are suffering from the disease. The authorities have seized a number of living hogs, as well as a quantity of pork, believed to be infected with the dangerous parasite. The outbreak is stated to be due to the German habit of eating uncooked ham, and often pork, in a half-raw state.

THE official returns as to vaccination show that in Leicester during the past twelve months, out of 5000 births only 550 children were vaccinated, of whom 39 were vaccinated by private medical men, the remainder being vaccinated at public vaccination stations.

A CASE of scurvy being reported on board the sailing ship *Castle Roy* on reaching the Victoria Dock from Calcutta, the port sanitary authority of London has ordered an inspection of all the ship's provisions.

IN Southern Russia, hydrophobia, during the past few weeks of abnormally hot weather, appears to have become epidemic; and the Pasteurian Hospital at Odessa is overwhelmed with cases.

GERMAN Medical Science has suffered a severe loss by the sudden death of Professor Möller at Königsberg.

BACTERIOLOGICAL RESEARCH.

THE study of animal and vegetable micro-parasites—protozoa, bacteria, and the more highly organised micro-fungi—has created a marvellous activity in the field of pathological inquiry. In nearly all the large medical and veterinary schools on the Continent, laboratories have been established or provision in some way made for instruction and research in bacteriology. As a result, the credit of the discoveries which have been made falls almost entirely to French and German investigators. And so rapidly has the new science progressed, that the text-books of pathology have been rewritten; the literature on the subject itself includes many volumes and a mass of scattered papers in scientific and medical journals; and even periodicals are now issued which are devoted almost, if not entirely, to pathological mycology. In this country it is only quite recently that the medical and veterinary professions and the public generally have been thoroughly aroused to a sense of the necessity for paying more attention to pathogenic micro-organisms. The agriculturist and the breeder of stock have been led to appreciate how seriously these micro-parasites affect the welfare of their crops and animals respectively. The public has awakened to the knowledge that human beings are not only liable to be directly attacked, but they may also fall victims through the medium of the lower animals. A wide field for investigation is thus open on the lines of Pasteur's valuable researches on the silkworm disease, fowl cholera, anthrax, and rabies, and of Koch in his brilliant researches in connexion with the etiology of tuberculosis. Several investigators in this country have taken up the question of the transmission of diseases from animals to man, such as tuberculosis, scarlet fever, and diphtheria. But there is ample room for many more investigators in the same and similar fields. There is both much to be done and to be undone. The first necessity is the instruction of those who wish to undertake bacteriological researches, so that they may be competent to start as independent investigators. The study requires a practical knowledge of the recent advances in microscopy and of the biological methods which are essential for keeping the organisms under continuous observation, and for gaining an insight into their life-history; while pathological histology, chemistry, and experimental pathology must all be made use of in endeavouring to determine the exact part micro-organisms play in the production of morbid phenomena. Such work, to be thoroughly and completely done, is almost of necessity beyond the reach of those who are otherwise actively engaged in the practice of their profession. Like the work of the professional analyst or any other expert, it must fall almost entirely into the hands of specialists. Access to a laboratory equipped with all the necessary apparatus, incubators, sterilisers, &c., is essential, while help from the laboratory assistants in the purely technical details, such as the preparation of the nutrient media, is necessary to effect a vast saving of time. But apart from undertaking laborious original researches, a practical acquaintance with the subject is of unquestionable value. The detection of the tubercle bacillus in the sputum dispels any doubt which may exist as to the nature of the case in question. The detection of the anthrax bacillus with equal certainty enables a diagnosis to be made in a case in which there might otherwise be considerable difficulty in arriving at a definite conclusion. The detection of the characteristic fungus in actinomycosis reveals at once the nature of a tumour which has been, and often still is, described by a variety of names which convey no idea whatever of the real character of the disease. And yet how few practitioners there are in either the medical or the veterinary profession who are acquainted with the appearance of these organisms and the technique for rapidly demonstrating them under the microscope. "A little knowledge is a dangerous thing" is a saying which applies very forcibly to bacteriology. It is not enough to be simply aware of the fact that a particular micro-organism is to be found in a disease; its characteristics, especially its microscopical appearances, must be thoroughly familiar to the observer. Septic bacilli, for example, may readily be found in the blood of the spleen some hours after death, and the untrained practitioner on the look-out for "rods" may only too readily jump to the

Digitized by Google

conclusion that he has encountered a case of anthrax. The need for practical instruction as well as for facilities for original research has been increasingly felt during the past two or three years. In another column we have given particulars of the new laboratory at King's College, by which this want will be supplied. We hailed with satisfaction the announcement last spring that arrangements had been made for a course of lectures and practical instruction in Bacteriology, or what might less conveniently but more correctly be termed Human and Comparative Micro-parasitology. The applicants for admission, consisting principally of medical officers of health from various parts of the country and veterinary surgeons, were very numerous, and several had to be refused owing to the limited accommodation. To meet the demand, the Council of King's College, with commendable foresight, have set aside one of the largest lecture rooms in the College to be equipped as a bacteriological laboratory, while two extra rooms are in process of erection for the Professor Superintendent and his assistants. Courses of instruction, with lectures, will be given in November and April, and there will be ample accommodation all the year round for those wishing to work privately or to undertake original researches. We are glad to think that London will at last be provided with a laboratory which will bear comparison very favourably with Professor Koch's laboratory in Berlin.

WOMEN AND LIFE ASSURANCE.

To say that the world owes the modern system of life assurance to women would be only a strong way of putting what is an undeniable and even commonplace fact—namely, that the great majority of life assurance contracts are entered into for the benefit of women, and under a sense of the duty which a man on whom a wife, a sister, or a mother is dependent, owes her, to provide against leaving her destitute in the event of his premature decease. The scheme of life assurance enters, indeed, in a vast variety of ways into our modern social relations. It makes numberless business arrangements possible which without it would be impracticable by reason of the life risks involved, and serves most usefully to cure, or at least reduce, the hardships growing out of unwise settlements and other unfortunate dispositions of property. But, taken altogether, these do not constitute probably even any considerable proportion of the vast aggregate of something like £430,000,000, which represents the collective contingent liability of the ordinary life assurance companies at present doing business in the United Kingdom. "Remember your wife and family" is the admonition with which the life assurance agent clinches his argument in ninety-nine colloquies out of a hundred; and it is a consideration which generally and properly prevails. He is but a poor sample of humanity—and, happily, exceptional—who can either consider with equanimity or dismiss from his thoughts the prospect of ruin in a home which, maintained in comfort by his own exertions, is unprotected against the pecuniary disaster of his decease. Thus female, or, to speak more generally, domestic, influences have been, and always will be, the principal "exciting cause" of life assurance.

But women, who have taken so preponderating a share heretofore in the benefits of life assurance may be expected in future to acquire a new interest in it, not only as beneficiaries, but also as life-risks. It is the obvious outcome of existing conditions. Never in our national history has the number or proportion been so great as now of women who enjoy separate incomes, whether derived from property or the fruit of their own toil. Where there is property, there, of course, its responsibilities will fall, and thus arise in relation to a large proportion of the female population the very same conditions which have given occasion for life assurance in the past. The practice will speedily follow upon the heels of the occasion, and there can be no doubt that the near future will witness a very large extension of life assurance operations along these lines. The omens are indeed so clear that both the Legislature and the companies have laid themselves out to cultivate this field. The Married Women's Property Act of 1882 gave to women the power to effect trust policies similar to those by which under the Act of 1870 married men had been able to put the proceeds of a life assurance policy beyond the reach of creditors, and in many ways the representatives, both in the press and in society, of the life assurance interest have been manifesting an awakening sense of the value for business purposes of the female life.

The taking of a new departure is not, however, altogether as simple as might be supposed. We can well imagine that women, as a rule, are not quite so easily accessible as men to the life assurance agent; but, be that as it may, it is certain that the female life has quite a distinct status from the male, and should theoretically be provided for by different tables. To some extent this is recognised by the insurance companies, and provision is made accordingly. It is well known that observation shows the female to be more tenacious of life than the male, and this advantage becomes more marked as years advance. Indeed, throughout the childbearing period the female community is at a relative disadvantage, and it is not until about her fiftieth year that the woman begins to enjoy an assured vital superiority over the man. Such things need of course to be taken into account, and it must be admitted that the materials do not at present exist for determining with any certainty whether or not the strain of "business" life is prejudicial to the female constitution. There are some grounds for suspecting that the superior longevity of elderly women as compared with men of equal years would disappear if the two classes could be made to exchange conditions of life; but of that we shall know more as the science of vital statistics becomes more complete. At present an opinion on that point must be very largely conjectural.

To a certain extent, then, the actuaries in providing for female life assurance are, for the present, condemned to work in the dark. But this is not so in regard to the adaptation of what materials are at hand to the special needs of a female class. It is doubtless true that the call for a new development arises out of the growing assimilation of female to male requirements. But the assimilation is and can only be partial. Speaking broadly, it may be said that while the principal object and use of life assurance must in all cases be the provision against premature decease, the subordinate purpose of making provision for old age by this means is relatively much more important in the case of a woman than of a man. Hence deferred annuities and benefits of that class assume an importance in this connexion quite distinct from what they have in other circumstances. In this and other ways it is possible so to mould and adopt a scheme of life assurance as to give it a wholly new character, and one fitted for a new career. Changes and adaptations of this sort are being gradually, and, as we think, very usefully, made by those who manage life assurance business.

With regard to a medical examination, we would remark that it is often much more formidable in imagination than in reality. Many persons, both men and women, shrink from it as they might from a serious surgical operation. Of course, this is simple folly. The underlying fear, no doubt, is that something may be found "wrong." It certainly needs but little philosophy to see that this is not only a weak, but also a mischievous apprehension. If anything *is* "wrong," the sooner the discovery is made the better; and, on the other hand, what happens in the very great majority of cases is that the proposer gets a clean bill of health, and goes away feeling as if he had renewed his lease of life. The result in any case is well worth the small amount of time and inconvenience involved in undergoing the examination. In truth, the chief part of an examination for life assurance consists usually in question and answer. The nature of the physical examination must, of course, in a large measure depend upon the indications afforded by the appearance of the proposed life and the facts elicited by the oral examination. This is, indeed, a matter in respect of which much must, and very much ought to be, left to the discretion of the examiner. The fact is one which the directors of insurance companies would do well habitually to bear in mind. The schedules of questions which they commonly furnish to their medical examiners usually err upon the safe side, that is to say they are apt to be over-full of detail. This must be so. They are intended not only to bring every possible point to the examiner's mind, but also in many cases to take the measure of any lesion that may be discovered. Hence the very formidable proportions to which some of them extend. Such exuberance does not matter so long as it is clearly understood that the company respects the examiner's discretion, and will consent to forego details which he,

Digitized by Google

having the proposer before him, may judge to be immaterial. Insistence upon the minutiæ of a report, while it does not add to the value of the result obtained, does add seriously to the irksomeness of the examiner's duty, and puts a real, though perhaps somewhat imaginary, difficulty in the way of proposers. Remove all unnecessary obstacles is obviously the present watchword of the insurance companies. And they are right. Vast as are their operations, they have still a large field to conquer, and, at any rate so far as ladies are concerned, they will find it to their advantage to repose a large confidence in the practitioner who is charged with the responsible and delicate duty of the medical examination.

THE INTERNATIONAL MEDICAL CONGRESS.

In general session of the forthcoming Congress, the following addresses will be delivered:—Dr. Austin Flint of New York, "Fever: its Causes and Rational Treatment"; Dr. Mariano Semmola of Naples, Italy, "Bacteriology, and its Therapeutical Relations"; Dr. P. C. Unna of Hamburg, Germany, "The Relations of Dermatology to General Medicine"; Dr. C. Fielding Blandford of London, England, "The Treatment of Recent Cases of Insanity in Asylums and in Private Houses"; Dr. A. Lutaud of Paris, "The Influence of Discoveries of American Surgeons on the Development of Gynæcology in Europe"; and Dr. Neudorfer of Vienna, "The Military Medicine of the Present and that of the near Future." The session is so organised that general meetings will be held on each morning of the week, and meetings of the sections during the later hours of each day.

Diseases of Children.

The following is the complete programme of this Section:—Professor J. Lewis Smith of New York, Chairman. The Section will hold its first session at 3 P.M. Monday, Sept. 5th, when the following papers will be presented:—1. An Investigation to determine whether the Absence of Sewage and of Water Pollution diminishes the Prevalence and Severity of Diphtheria, by Dr. C. W. Earle of Chicago. 2. Rate of Growth in American and British Children, and its Bearing on the Investigation of Diseases, by Professor W. Stevenson of Aberdeen, Scotland. 3. Diseases of Faulty Habit, by Dr. James F. Goodhart of London, England. 4. Deleterious Results in Children of a Narrow Prepuce and Preputial Adhesions, by Professor L. A. Sayre of New York.

At Tuesday's sessions the following papers will be read: 1. The Milk Supply of Cities; Adulterations and Modes of Detecting Them, by Dr. Cyrus Edson of New York. 2. The Nutrition of Infants, by Professor Albert Leeds of Stevens Institute, Hoboken, New Jersey. 3. The Use of Cow's Milk in the Feeding of Infants, by Professor W. C. Vaughan, University, Michigan. 4. Anatomical Characters of Membranous Croup as observed in fatal cases in the New York Foundling Asylum, by Dr. W. P. Northrup. 5. Remarks on Tubage of the Glottis, and the manner in which it was practised in France, by Dr. H. Bouchet of Paris. 6. Intubation of the Larynx, with demonstration on the living subject, by Dr. Joseph O'Dwyer and Dr. Dillon Brown of New York. 7. Intubation *versus* Tracheotomy in the Treatment of Croup, by Professor F. E. Waxham of Chicago.

At Wednesday's sessions the following papers will be read:—1. The Treatment of Strumous Glandular Enlargement of the Neck, by Dr. Martin Oxley of Liverpool, England. 2. Infantile Convulsions in connexion with after Neurotic Tendencies, by J. A. Coutts of London, England. 3. A Study of some of the Bacteria found in the Dejecta of Infants affected with Summer Diarrhœa, by Dr. W. D. Booker of Baltimore. 4. Hallucinations in Young Children, by Dr. E. Bouchet of Paris. 5. Cerebral Irritation in Children, by Dr. Jules Simon of Paris. 6. Treatment of Diphtheria by Antiseptic Sprays, by Dr. Grancher of Paris. 7. Treatment of Physiological Derangements in Children due to Over-feeding, by Dr. Cadet De Gassicourt of Paris. 8. Notes of Malaria of Children in Brazil, by Dr. Moncorvo of Rio de Janeiro.

At Thursday's sessions the following papers are announced:—1. Observations regarding True Pneumonia in Children, by Professor A. D'Espine of Geneva, Switzerland. 2. Paper by Professor Oscar Wyss of Zurich, Switzerland. 3. Some Observations on Headaches in Children, and their Relation to Mental Training, by Dr. W. M. Day of London, England. 4. Scarlatinal Nephritis from a Clinical and Pathological Standpoint, by Dr. Henry Ashley of Manchester, England. 5. On the Pathology of Scarlatinal Nephritis, by Dr. Frank Grauer. 6. The Contagious Principle of Pertussis, by Professor A. Vogel of Munich. 7. The Nature of Whooping-cough, and its Antiseptic Treatment, by Dr. Moncorvo of Rio de Janeiro. 8. On Acetonuria in Children, by Dr. A. Baginsky of Berlin, Germany. 9. Hereditary Syphilis and Rachitis in Brazil, by Dr. Moncorvo of Rio de Janeiro. 10. Marasmus, by Dr. J. N. Love of St. Louis, Mo.

At Friday's sessions the following papers will be read:—1. The Treatment of Lateral Curvature, by Dr. J. Knight of New York. 2. Anchylosis of the Knee-joint in the Straight Position by Excision as a Remedy for the Atrophy and Deformity following Acute Poliomyelitis of Childhood, by Professor Stephen Smith of New York. 3. Hip Disease, Practical Points in its Treatment, by Dr. A. J. Steele of St. Louis, Mo. 4. Forcible Correction of Contracted Knee-joint, by Dr. E. W. Bradford of Boston, Mass. 5. Progress of Orthopædic Surgery, by E. Noble Smith of London, England. 6. Section of Contractured Tissues essential before Mechanical Treatment can be effectual, by Professor Lewis H. Sayre of New York. 7. The Scope and Limitations of Orthopædy, by Dr. C. F. Taylor of New York.

Anatomy.

The following is a list of papers proposed to be read in the Section on Anatomy:—The Bladder, by Reginald Harrison, F.R.C.S., &c., Liverpool, England. The Wolffian Bodies, by Wm. Mitchell Banks, M.D. Ed., F.R.C.S., &c., Liverpool, England. A paper (subject to be announced), by Professor E. Frommann, Jena, Germany. The Intercerebral Nerve Tracts in the Light of Atrophy Methods of von Gudden, by B. C. Spitzka, M.D., &c., New York. On the Development of the Torus Longitudinalis in Teleosians and its Homology in higher Vertebrates, by Professor Rabe Rückard, M.D., &c. On the Surgical Collateral Branch of each of the Main Arteries of the Human Body, by Edward Souchon, M.D., New Orleans, La. A Contribution to the Pathology of Hip Disease, by Milton Josiah Roberts, M.D., New York. Anatomy of the Male Urethra and its relation to Stricture, by E. R. Palmer, M.D., Louisville, Ky. Does a Relationship exist between Anomalies of the Visual Apparatus and the so-called "Neuropathic Tendency?" by A. L. Ranney, M.D., New York. A paper (subject to be announced) by Thomas G. Morton, M.D. Compression Myelitis in Pott's Diseases, by George R. Elliott, M.D., New York. Anatomy of the Foot and its relation to the Operation of Tenotomy, by Lewis Hall Sayre, M.D., N.Y. Anatomy of the Bladder and its relation to Rupture, by I. N. Bloom, M.D., Louisville, Ky. Dissection of a very Young Human Embryo, by Augustus C. Bernays, St. Louis, Mo. On the Urethra, by Reginald Harrison, F.R.C.S., &c., Liverpool, England. Anatomy and Surgical Importance of the Renal Capsule and the Perirenal Adipose Tissue, by L. H. Dunning, M.D., &c., South Bend, Ind. Specimen, by W. T. Oppenheimer, M.D., &c., Richmond, Va. The Didactic Teaching of Human Anatomy, by F. W. Langdon, M.D., &c., Cincinnati, Ohio. A Contribution to the Pathology of Spinal Caries, by Milton Josiah Roberts, M.D., &c., New York. Umbilical Cord, by C. W. Kelley, M.D., &c., Louisville, Ky. Frozen Sections of the Male Pelvis showing relations of Peritoneum to Rectum, Bladder, and Median Line of Abdominal Wall, with special reference to Suprapubic Cystotomy, by Albert B. Strong, M.D., &c., Chicago, Ill. The Mesocephalon of the True Reptile, by B. C. Spitzka, M.D., &c., New York. The Anatomy of the Rectum and its relation to Reflexes, by J. M. Matthews, M.D., &c., Louisville, Ky. Paper (title not announced), by L. S. McMurtry, M.D., &c., Danville, Ky. Studies in Brain Surgery, by Hal. O. Wyman, M.D., &c., Detroit, Mich. The Peritoneum and its relation to Injuries of the Bladder, by N. B. Carson, M.D., &c., St Louis, Mo. Contribution to the Pathology of Knee-Joint Diseases, by Milton Josiah Roberts, M.D., New York. The Groove of the Central Veins on the Inner Table of the Calvaria, by Frank R. Fry, M.D. &c., St. Louis, Mo. Anatomical Considerations concerning the Application of Plaster-of-Paris Dressings to Fractures of the Femur, by W. B. Rogers, M.D., &c., Memphis, Tenn. The Anatomy of the Urethra and Prostate Gland and Bladder, with special reference to Surgical Relief for Enlarged Prostate in Old Men, by Wm. C. Wile, M.D., &c., Philadelphia, Pa. Presentation of Anatomical Specimen, by George Benjamin Johnston, M.D., &c., Richmond, Va. Anatomical Points involved in Loss of Complete Scalp, including one Ear and greater portion of the Eyelids, by F. C. Schaefer, M.D., &c., Chicago, Ill. The Colon, by S. K. Crawford, M.D., &c., Chicago, Ill. Anomalies of the Middle Thyroid Artery, with presentation of Specimen, by Max J. Stern, M.D., &c., Philadelphia, Pa. The Anatomy and Relations of the Cæcum and Vermiform Appendix, with special reference to the Surgery of the Parts, by Hermann M. Briggs, M.D., &c., New York. On Comparison of Twenty Superior Maxillary Bones, by E. M. Wilson, M.D., &c., Bridgeport, Conn. The Destruction of Dissection-room Offal, by H. C. Boenning, M.D., &c., Philadelphia, Pa. Anatomical Points of Value in the Diagnosis and Treatment of Some of the Joint Affections, by N. Stamm, M.D., &c., Fremont, Ohio. A Plea for some Reforms in the Present Methods of Teaching Anatomy, by Wm. Perrien Nickson, M.D., &c., Atlanta, Ga. The Anatomy of the Vermiform Appendix, with some of its Anomalies, by F. M. T. McKennan, M.D., &c., Pittsburg, Pa. The Proper Methods of Teaching Anatomy, by A. P. H. Leuf, M.D., &c., Philadelphia, Pa. Paper (title not announced), by Joseph Dickson, M.D., &c., Pittsburg, Pa. Reports of Three Cases of Nephrectomy, with special reference to the Anatomy, by Geo. Halley, M.D., &c., Kansas City, Mo. The Anatomy of Stricture, by J. Kneely Rhodes, M.D., &c., Philadelphia, Pa. The Pivotal Point in Anatomy and the Principle Underlying it, by W. H. Triplet, M.D., &c., Woodstock, Va.

HOLIDAY COLONY IN SPAIN.

El Siglo Médico states that a small "holiday colony" of eighteen poor children, belonging to the public elementary schools of Madrid, has just been taken by Señor Cosio, Director of the Pedagogic Museum, and two schoolmasters to San Vicente de la Barquera, where they will remain a month. This is the first "holiday colony" which has been publicly arranged in Spain, and seems to have excited a good deal of interest, the Inspector-General of Education, Señor Robledo, and a large concourse of people having attended to witness the departure of the little travellers. The Northern Railway Company, too, has exhibited its willingness to participate in this useful scheme by making a reduction of 75 per cent. on its fares for the benefit of those comprising or accompanying the colony. Though the number of children is very small, it is to be hoped that in future years means may be found to extend the boon to a far wider circle.

M. AUDRY ON THRUSH.

M. AUDRY, writing on the evolution of the fungus of thrush in the *Revue de Médecine*, states that he finds it can be cultivated just as well in neutral or alkaline media as in those which have an acid reaction. This tends to diminish the importance which has usually been attributed to the acidity of the mouth in the etiology of thrush. It is, he thinks, possible that this acidity is the consequence rather than the cause of the spread of the disease, for he has remarked that broth cultures of the fungus which were neutral at the commencement of the experiment became slightly acid. It was found to develop well in media containing glycerine, but not in pure glycerine. It could not be cultivated in broths containing borax, so that M. Audry's observations tend to confirm and justify the practice of treating thrush by local applications of this substance

Digitized by Google

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

DUNLOP, JAMES C., M.B., C.M., M.R.C.S., has been appointed Resident Surgeon to Chalmer's Hospital, Edinburgh.

DUNSTAN, ROBERT, M.R.C.S., L.S.A., has been appointed Medical Officer for the St. Just District of the Truro Union.

GRIFFITH, T. WARDROP, M.B., C.M., has been appointed Professor of Anatomy in the Yorkshire College, Leeds.

GROSS, CHARLES, M.B., B.S.Lond., F.R.C.S.Eng., has been appointed Medical Superintendent of the New Infirmary at Champion-hill of the St. Saviour's Union.

GWYNNE-HUGHES, DEVEREUX, L.R.C.P., L.R.C.S.Ed., has been elected Resident Medical Officer at the Sydney Hospital.

JONES, DANIEL M., M.D., C.M.Ed., has been appointed Medical Officer for the Marske District of the Guisborough Union.

KING, THOMAS RADFORD, M.D.Ed., has been appointed Medical Superintendent of the Lunatic Asylums at Porirua and Wellington, New Zealand, vice Levinge, transferred.

LEVINGE, EDWARD GEORGE, M.B.Dub., L.R.C.S.I., has been appointed Medical Superintendent of the Christchurch Lunatic Asylum, New Zealand, vice Hacon, resigned.

OLIVER, JOHN W., M.D., M.Ch., M.A.O. Roy. Univ. Irel., has been appointed Assistant Medical Officer to the Hackney Infirmary, Homerton, E., vice R. Evans, M.R.C.S., L.R.C.P., resigned.

WILLIAMS, W. C., has been appointed Analyst for the County Palatine of Lancaster.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ABERDEEN UNIVERSITY.—Six Examiners for Graduation in Medicine. Grant £30 per annum.

BETHLEM HOSPITAL.—Two Resident Medical Students. Apartments, rations, and attendance.

BRITISH HOSPITAL, Buenos Ayres, South America.—Resident Medical Officer. Stipend £200 per annum, increasing to £250, together with an annual allowance of £20 for wine, furnished apartments, board and washing.

DENBIGHSHIRE INFIRMARY, Denbigh. — House-Surgeon. Salary to commence at £85 per annum, with board, residence, and washing in the house.

DEVON AND EXETER HOSPITAL. — House-Surgeon. Salary £120 per annum, increasing £10 per year to £150, with board and lodging.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Two Resident Clinical Assistants. Board and lodging, but no salary.

HOSPITAL FOR WOMEN, Soho-square, W. — Clinical Assistants. Fee five guineas.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Pathological Curator.

ST. LUKE'S HOSPITAL. — Resident Clinical Assistant. Board and residence.

SHEFFIELD GENERAL INFIRMARY.—Two Assistant Physicians and two Assistant Surgeons.

WESTERN DISPENSARY, Rochester-row, Westminster, S.W.—Attending Medical Officer.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On the 28th ult., at Afnslie-place, Edinburgh, the wife of J. Graham Brown, M.D., F.R.C.P.E., of a daughter.

BUNN.—On the 28th ult., at Berndale, Upper Norwood, the wife of C. Grinling Bunn, M.R.C.S., L.R.C.P., of a daughter.

GRANGE.—On the 29th ult., at Mansfield House, Moffat, N.B., the wife of W. D'Oyly Grange, M.D., of a son.

PERN.—On the 25th ult., at Botley, Hants, the wife of Alfred Pern, F.R.C.S., of a son.

THOMPSON.—On July 28th, at Madras, the wife of Surgeon C. M. Thompson, Indian Medical Service, of a daughter.

MARRIAGES.

ARTHY—FINDLAY.—On the 31st ult., at the Parish Church, Stretford, Lancashire, George F. S. Arthy, M.R.C.S., to Annie Eliza, eldest daughter of Bruce Findlay, of the Royal Botanical Gardens, Manchester.

FENTON-JONES—FOSTER.—On the 25th ult., at St. James's Church, Tatham, by the Rev. Arthur W. Foster, assisted by the Revs. E. Denny and J. C. Hyatt, William Hugh Fenton-Jones, M.D., A.M.Oxon., to Alice, eldest daughter of the late William Foster, of Hornby Castle, Lancashire, and Harrowins, Yorkshire.

JACKSON—RAY.—On the 26th ult., at St. Mark's, North Audley-street, Allan Heslop Jackson, M.R.C.S., to Eva Lindley, elder daughter of James Ray, M.R.C.S., of Lowestoft.

RANDALL—BEAUFOY.—On the 16th ult., at Coity Parish Church, Bridgend, Glamorganshire, Wyndham Randall, M.R.C.S., L.R.C.P.Ed., to Emma, youngest daughter of the late John Beaufoy, of Coventry.

DEATHS.

DEFRIEZ.—On the 29th ult., at Bethnal-green-road, Joseph George Defriez, M.R.C.S., aged 66.

DICKSON.—On the 7th ult., at St. Julien's, Malta, Sir Joseph Ritchie Dyon Dickson; for forty years Physician to Her Majesty's Legation at the Court of Persia.

MITCHELL.—On the 26th ult., at Walton-on-the-Naze, Jas. Barr Mitchell, M.D., L.F.P.S., of Titchfield-terrace, Regent's-park, and formerly of Paris, aged 69.

NICOLSON.—At Cumberland-street, Edinburgh, John Balfour Nicolson, M.D., R.N., aged 68.

IN MEMORIAM.

WAKLEY.—On August 30th, 1886, at Heathlands-park, Longcross, Chertsey, Surrey, James Goodchild Wakley, M.D., for twenty-five years Editor of THE LANCET, youngest son of the late Thos. Wakley, M.P.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

To Correspondents.

WE tender our best thanks to those gentlemen who have kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.

The present number being principally devoted to information especially interesting to students, we are necessarily compelled to defer the publication of communications on other important subjects.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
TO CHINA AND INDIA		One Year	1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES		Ditto	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Inaugural Address

DELIVERED AT THE

NINTH INTERNATIONAL MEDICAL CONGRESS,

Held at Washington, U.S., in September, 1887,

BY NATHAN SMITH DAVIS, M.D., LL.D.,

PRESIDENT OF THE CONGRESS.

GENTLEMEN,—With a full consciousness of my own deficiencies, and still with a heart overflowing with gratitude, I thank you for the honour you have bestowed in selecting me to preside over the deliberations of this great and learned assembly. It is an honour that I appreciate as second to no other of a temporal nature, because it has been bestowed neither by conquest nor hereditary influence, nor yet by partisan strife, but by the free expression of your own choice.

Addressing myself now more directly to those here assembled, who have left homes and loved ones in other lands and encountered the fatigue and danger of travelling by sea and by land, in the name of the medical profession of this country I welcome you, not only to this beautiful city and the hospitality of its citizens, as has been so admirably done already by the honourable representative of the Government who has just taken his seat, but I cordially welcome you to the open arms and warm hearts of the medical men of *this whole country*, in whose name you were invited here three years since, and whose representatives are now here side by side with you, gathered from the east, the west, the north, the south, as well as from the rugged mountains and fertile valleys of the centre, to make good the promise implied by that invitation. If they do not cause you to feel at home and happy, not only in the social circles and halls devoted to the advancement of science, literature, and art in this city of our nation's pride, but wherever you may choose to roam, from the rocky coast of New England on the Atlantic to the Golden Gate of the Pacific, it will be from no want of earnest disposition to do so.

And now, I not only thus welcome you from other lands, but I take great pleasure in greeting you one and all as leading representatives of a profession whose paramount object is the lessening of human suffering, by preventing, alleviating, or curing diseases wherever found, and in whatever class or grade of the human family. Nay, more, with profound reverence I greet you as a noble brotherhood, who, in the practical pursuit of that one grand object, recognise no distinction of country, race, or creed, but bind up the wounds and assuage the pains of the rich and poor, ruler and ruled, Christian and pagan, friend and foe alike. Not that every medical man does not love and defend his own country and fireside with as fervid a patriotism as the members of any other class of men. But as disease and pain are limited to no class or country, so is the application of his beneficent art limited only by the number of those suffering within his reach. With a common object so beneficent in its nature, and opportunities for its practical pursuit so universal, it is but natural that you should be found searching for the most effectual means for the accomplishment of the one object of lessening human suffering in every field of nature and in every department of human knowledge.

The living human body—the chief object of your solicitude—not only combines in itself the greatest number of elementary substances and the most numerous organs and varied functions, so attuned to harmonious action as to illustrate the operation of every law of physics, every known force in nature, and every step in the development of living matter from the simple aggregation of protoplasm constituting the germinal cell to the full-grown man, but it is placed in appreciable and important relations with the material objects and immaterial forces existing in the world in which he lives. Hence a complete study of the living man, in health and disease, involves a thorough study, not only of his structure and functions, but more or less of every element and force entering into the earth, the air, and the water with which he stands in constant relation.

The medical science of to-day, therefore, embraces not only a knowledge of the living man, but also of such facts, principles, and materials gathered from every other department of human knowledge as may increase your resources for preventing or alleviating his suffering and of prolonging his life. The time has been when medical studies embraced little else than the fanciful theories and arbitrary dogmas of a few leading minds, each of which became for the time the founder of a sect or so-called school of medicine, with his disciples more or less numerous. But with the development of general and analytical chemistry, of the several departments of natural science, of a more practical knowledge of physics, and the adoption of inductive processes of reasoning, the age of theoretical dogmas and of medical sects blindly following some more plausible leader passed away, leaving but an infinitesimal shadow yet visible on the medical horizon. So true is this, that in casting our mental vision to-day over the broad domain of medicine, we see its votaries engaged, some searching for new facts and new materials; some studying new applications and better uses of facts and materials already known; some of them are in the dead-house, with scalpel and microscope, not only studying the position and relations of every part from the obvious bones and muscles to the smallest leucocyte in health, but also every deviation caused by morbid action or disease. Some are searching the fields, the forests, the earth and the air, both for more knowledge concerning the causes of disease and for additional remedial agents; some are in laboratories, with crucible, test-glass, and microscope, analysing every morbid product and every remedial agent, separating the active principles from the crude materials and demonstrating their action on living animals; while far the greater number are at the bedside of the sick and wounded applying the knowledge gained by all other workers to the relief of human suffering. A more active, earnest, ceaseless, and beneficent field of labour is not open to your vision in any other direction or occupied by any other profession or class of men. And thus has the science of medicine become a vast aggregation of observed facts, many of them so related to each other as to permit practical deductions of permanent value, while many others remain isolated through incompleteness of investigations, and therefore liable to prompt, hasty, or even erroneous conclusions. Indeed, the most effective and embarrassing feature in the science and art of medicine at this time is the rapid accumulation of facts furnished by the vast number of individual workers, each pushing investigations in some special direction without concert with his fellows, and without any adequate conception of the coincident lines of observation necessary to enable him to see the true bearing of the facts he evolves. Hence he is constantly mistaking mere coincidences for the relation of cause and effect, and the pages of our medical literature are being filled with hastily formed conclusions and rules of practice from inadequate data. This results, in part at least, from the extent and variety of the fields of inquiry and the complexity of the problems presented for solution. For nowhere else within the realms of human thought does the mind encounter problems requiring for their correct solution the consideration of a greater number of data than in the study of etiology and pathology. To determine the appreciable conditions of the earth, air, and water of any country before, during, and after the invasion of an epidemic disease long enough to include several consecutive visits of the same, is not possible for a single individual, nor for any number of observers acting separately or without concert. Yet just this complete knowledge is necessary to enable us to separate the conditions that are merely coincident or accidental from those that are such constant accompaniments of the disease as to prove a necessary relation between them. And it is only by such persistent, coincident, systematic observations of many individuals, each having a definite part, and the results carefully compared analytically and synthetically at proper intervals, that the real conditions and laws controlling the prevalence and severity of epidemics and endemics can be clearly demonstrated. It is not enough to discover the primary infection, or the *contagium vivum*, whether it be the bacillus of cholera, yellow fever, or tuberculosis, for abundant experience has shown that not one of these will extend its ravages in any community or country unless it finds there is a soil or pabulum congenial for its support and propagation.

Digitized by Google

It is on the development and diffusion of knowledge concerning the local conditions necessary for receiving and propagating the specific infections of disease that nearly all the important sanitary measures of modern times have been based. And it is on a further development of knowledge in the same direction, gained by more systematic, continuous, and coincident investigation, that we shall most successfully protect our race from the pestilences that have hitherto "walked in darkness and wasted at noonday." It was the extensive and ever-extending field of medical science, the complexity of the problems pressing for solution, and still more the individual responsibility of applying the resources at command to the direct treatment of disease, that early disposed medical men to seek each other's counsel, to form groups or clubs for comparison of views and mutual improvement. The manifest advantages of these soon prompted more extended social gatherings, until at the present time a large proportion of the more active members of the profession in every civilised country are participating in municipal, district, national, and international medical organisations. The aggregate benefit derived from all this active intercourse is beyond easy expression in words. In the more frequent and familiar comparison of cases and views on all professional subjects in the local societies, closer habits of observation and a wider range of thought are induced, while narrow prejudices and bigotry give place to generous rivalry and personal friendships. In the larger gatherings, the formal preparation of papers and reports on a great variety of subjects impels their authors to a wider range of study and greater mental discipline, while the collision with other minds in discussion brings all aspects of the subject to view, enlarging the scope of mental vision, starting new trains of thought, and begetting a broader and stronger mental grasp with purer and nobler aims in life.

I think I am justified in saying that no other one influence operative in human society during the present century has done as much to develop and diffuse medical knowledge, to stimulate its practical and successful application, both in sanitary measures for preventing disease and in the direct alleviation of suffering at the bedside, and in unifying and ennobling the profession itself, as has been accomplished by the aggregate medical society organisations of the world. Yet their capacity for conferring other and perhaps still greater benefits, under proper management, will have become manifest in the near future. And that I may accomplish the chief object of this address, I must ask your indulgence while I indicate some of the more important additional benefits in advancing medical science and saving human life through the instrumentality of our medical society organisations, and the methods by which they may be accomplished.

Every experienced and intelligent practitioner of the healing art is familiar with the fact that all acute general diseases are influenced in their prevalence and severity by seasons of the year, topographical and other conditions of the earth, meteorological conditions of the atmosphere, and the social condition and habits of the people themselves. The most familiar endemics vary annually in the same localities, while the great epidemics that have for ages broken over the comparatively limited boundaries of their habitats only at intervals of years, and extended their ravages from country to country, and receded again to the source from which they apparently originated, differ widely in the different periods of their prevalence. But in studying the essential causes of any one of these general diseases and the laws and conditions under which such causes operate, he soon finds certain factors, essential for the solution of his problems, wanting. For instance, if he wishes to identify the date of the first attack of epidemic cholera in a given locality, and the character of bowel affections immediately preceding, the ordinary statistics of mortality will give him only the date of death, which may have been from one to seven days later, or it may have been preceded by one or more cases that recovered. If he is anxious to determine the reason why the disease, on entering one community, develops with such rapidity that in a few days its victims are found in every grade of the population and in almost every street, while in another it develops slowly, adhering persistently to particular classes or localities, he may find in the ordinary meteorological records the thermometric, barometric, and hygrometric conditions of the atmosphere, with the direction and the velocity of the winds, but he finds nothing regarding those important though variable elements known as ozone and hydrogen peroxide, active oxidisers; or those nitrogenous products called free and albuminoid ammonia. Neither do the sanitary records give the desired information concerning the composition and impregnations of the soil, or of the organic and inorganic emanations that may arise therefrom. An adequate knowledge of these absent factors relating to the condition of the earth, air, and water over districts large enough to embrace localities subject to invasions of the epidemics and others known to be exempt, through a sufficient length of time to cover several periods of prevalence and periods of absence alike, is essential for enabling us to comprehend the causes that make one district amenable to the prevalence of a disease and another not, as well as the marked differences in the severity and mode of progress of the same disease at different periods in the same localities and same classes of the people. The same additional knowledge would also furnish the basis for further sanitary measures of the greatest practical value. And yet it must be obvious that the co-operation of numbers of medical men directly engaged in the field of general practice, with others possessed of more practical facilities for chemical and microscopical research, is necessary for successfully prosecuting such coincident and continuous investigations as would be likely to secure the desired results. Only well-trained general practitioners in every locality chosen for observation could observe and record the date of the initial symptoms of acute general diseases coming under their notice, and at stated intervals collate and report them to a central committee. The daily observations concerning the presence and relative proportion of active oxidisers and of nitrogenous organic elements in the atmosphere and the water would require the selection of one or two experts in chemical and microscopical research for each locality, all making their observations coincidently in time and by uniform methods. There are included in the organised medical associations of each country the men and materials necessary for prosecuting every well-defined line of inquiry; and these associations, by their stated meetings and their facilities for intercommunication and concert of action, present the entire machinery needed, and are only waiting for well-planned and systematic use.

The tendency to make the permanent medical organisations available for prosecuting work in the directions I have indicated has already been manifested to a limited extent, as may be seen in the formation of the Collective Investigation Committee of the British Medical Association and of the International Collective Investigation Committee, organised during the sitting of the Eighth International Congress at Copenhagen. An earlier movement more fully of the character I have been endeavouring to explain was made by the American Medical Association in 1875,[1] when a standing committee was appointed to establish in a sufficient number of localities regular coincident daily observations and records concerning all appreciable meteorological conditions, including organic and inorganic elements found in the atmosphere, and the date of beginning of acute general diseases, and report the results at each annual meeting of the Association. The committee made reports embodying facts of interest and permanent value in 1877,[2] in 1879,[3] in 1881,[4] in 1882,[5] and in 1883.[6] The latter report contains, among other items, a complete tabulated statement of the free and albuminoid ammonia in the atmosphere for every day in the year ending Aug. 31st, 1883, as determined for the committee by Professor J. H. Long in connexion with the laboratory of the Chicago Medical College. The committee is still prosecuting its work with material in hand for a still more important report at an early day. The greatest difficulty encountered has been to enlist a sufficient number of active practitioners in each locality, who faithfully record the desired clinical facts and report the results to the committee. But this and all other obstacles can be overcome by persevering and well-directed work.

I trust no apology is needed for having embraced this occasion to attract your attention to the very important question how to make all our medical associations more useful in promoting the science of medicine by more complete methods of investigation, especially in directions where the coincident action of several persons in different places is essential for success. I fully appreciate the

great benefit resulting from the simple mingling of large numbers of medical men in social contact, where each is made to hear constantly, whether on the street, in the hotel, or the assembly room, new suggestions, new modes of expression, and to observe the physical and mental effects of the various habits and customs of the different peoples, until each one leaves the general gathering with largely increased mental activity and resources, as was so happily expressed by Sir James Paget in his address to the Congress of 1881 in London. And I appreciate in a still higher degree the benefits derived from the preparation and reading of papers by individuals, and the discussion of important questions, in all our assemblies. But, for reasons I have already briefly stated, I hope to see added in every permanent general medical society two standing committees: one, to whom should be referred for critical examination every communication claiming to embody a new discovery in either the science or art of medicine; and the other should be charged with the work of devising such lines of investigation for developing additional knowledge as require the co-operation of different individuals, and perhaps societies, and of superintending their efficient execution until crowned with success. If 10 or 20 per cent. of the money paid for initiation and membership dues by the members of each society were appropriated and judiciously expended in the prosecution of such systematic and continuous investigations from year to year, it would accomplish more in advancing medical science directly, and indirectly in benefiting the human race, than ten times that amount would accomplish if expended in any other direction. For it must be remembered that when money is expended for material objects, even for food, clothing, or medicine, such materials feed, clothe, or relieve but one set of needy individuals and are themselves consumed; but the expenditure of money and time in such a way as to develop a new fact capable of practical application either in preventing, alleviating, or curing disease—that fact does not, like the food or medicine, perish with the using, but it becomes literally imperishable. Neither are its benefits limited to one set of individuals, but it is transmitted with the speed of the lightning over the land and under the sea to every civilised people; and whatever benefits it is capable of conferring are as capable of being applied to a million as to one, and of being repeated with increasing efficiency from generation to generation.

It has been tersely and correctly stated that associated action constitutes the characteristic and predominating power of the age in which we live. It is by associated action that education in its broadest sense, religion, and civilisation have been more rapidly diffused among the masses of mankind during the present century than during any other period of the world's history. It is by the association of capital, wielded by the associated intellects of the nineteenth century, that highways of commerce have been opened over the valleys, through the mountains, across the deserts, and on the oceans, over some of which the material productions of the nations are borne by the resistless power of steam, and along others the products of mental action are moved with the speed of electric currents, until both time and space are so far nullified that the most distant nations have become neighbours, and the inhabitants hold daily converse with each other from opposite sides of the globe. Indeed, it is only by means of such of these highways as have been constructed within the memory of him who addresses you that you have been gathered in this hall from the four quarters of the earth, and through which an account of your doings may be daily transmitted to your most distant homes. I congratulate you on the fact that the profession you represent has taken the lead of all other professions or classes of men in rendering available these grand material achievements of the age for cultivating fraternal relations, developing and interchanging knowledge, and planning concerted action for rendering human life everywhere healthier, happier, and of longer duration.

This is the ninth grand International Congress in regular series within little more than two decades, and let us hope that all its work will not only be done in harmony and good order, but with such results as will add much to the aggregate of human happiness through all the coming generations. Without trespassing further on your patience, I must ask your forbearance with my own imperfect qualifications, and your generous assistance in the discharge of the responsible duties you have devolved upon me.

Clinical Lectures
ON
DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary,

BY C. BELL TAYLOR, M.D., F.R.C.S.,
HONORARY SURGEON TO THE INFIRMARY.

LECTURE VI.

GLAUCOMA.

GENTLEMEN,—When Mr. Mayhew, the late eminent veterinary surgeon, described rabies in the dog, he used to say: "The eyes, which glow like living coals in the early stages of the malady, become *bottle green*, and in many cases slough and fall from the sockets ere death closes the scene." Now I need not tell you that *glaucos* is Greek for green, and it is precisely this bottle-green reflex which you notice in the pupillary area of the patient you have just seen which is the origin of the term "glaucoma"—the subject of this evening's lecture. I know you will say: "If that is so, it is strange that this remarkable symptom should be conspicuously absent in so many of the cases which come under treatment at this institution." Well, it does seem strange; but the fact is, that the term as at present understood bears little relation to its original etymology, but is used indiscriminately to cover the whole series of morbid changes which are the result of increased intraocular tension or fulness of the globe. What is the cause of increased intraocular tension? Well, if you mean the primary cause—the *causa causans*,—all I can do in the way of response is to call your attention to certain facts which may assist you in forming an opinion. A lady addicted to play, but a bad loser, was one evening most unfortunate at cards. Under the influence of the chagrin so occasioned, she developed glaucoma and lost the sight of the right eye. Warned by this terrible mishap, she abandoned her favourite pastime for a year and a half, when, being tempted, she again ventured, was again unfortunate, and lost the sight of the remaining eye. (Fischer.) A distinguished engineer, during the siege of Paris, ascended in a balloon to make observations, was caught in a contrary current, driven within the enemy's lines, and taken prisoner. That same night he was attacked with glaucoma in both eyes. (Wecker.) A nurse, worn out with watching at the bedside of a dying patient, fell asleep and was suddenly roused by a loud crash. The sash cord had broken. Glaucoma came on within an hour in the right eye, and the left was speedily affected in the same way. (Lawson.) I could multiply such recitals from many similar cases occurring in my own practice, but here is evidence enough to show that misery and misfortune, anxiety and worry, stand in the relation of predisposing cause and effect to glaucoma, and that nervous shocks will precipitate an attack. Some pathologists affirm that the eye is affected through the medium of the fifth and ciliary nerves, others that the sympathetic is principally involved. However that may be, it is certain that the proximate or immediate cause of a rise in tension is one or other of two conditions—either secretion is in excess, or the normal outflow is impeded. The vitreous and aqueous chambers of the eyeball are, as you know, respectively permeated and filled with a watery fluid; if the former is removed, suspended, and pricked, it drains slowly away; if the latter is punctured, it escapes at once. But you will hardly appreciate without reflection the extraordinary rapidity with which this fluid circulates. The late Dr. Bence Jones demonstrated by actual experiment that a small dose of iodide of potassium appeared in the aqueous chamber almost simultaneously with its imbibition; and it is well known when fluorescine is injected under the skin that the play of colours is speedily perceptible in the pupil (Ehrlich). What is the mechanism of this wonderful process? How does this watery fluid get into the eye? and how does it get out of it? According to received physiological views, it is secreted by the choroid, iris, and pigment epithelium of the ciliary folds, permeates the vitreous chamber, passes backwards along the optic nerve, and forwards through the pupil into the aqueous chamber and canal of Schlemm,

Digitized by Google

whence it finds its way into the episcleral veins, and you can readily understand that any check to its outflow, or excess in secretion, must at once be attended with a rise in tension, and that is precisely what happens when a patient is said to be suffering from glaucoma. If the initial lesion is hypersecretion, the disease is primary or idiopathic; if the outlets are first blocked by accident or pre-existing disease, the affection is, of course, secondary; and it is well to remember that the causes which block the outlets are apt also to excite irritative hyper-secretion, and that excessive secretion, by pushing forward the lens and iris base, is also certain to impede the normal outflow, so that the disease moves in a vicious circle and tends continually to get worse. Primary glaucoma seldom occurs under fifty years of age, and only then, as a rule, in persons with a certain predisposition, but secondary glaucoma may be induced at any age and needs no predisposition. The infant sent here last week by Dr. Walker had marked glaucoma, the result of hæmorrhage between the choroid and retina. It may also proceed from almost any inflammatory affection of the eye, and from various accidents, injuries, and surgical operations. "It is mournful," says von Graefe, "to see how many eyes, after escaping entire destruction from ulceration, as in ophthalmia neonatorum, are afterwards rendered blind by secondary glaucoma, the result of adhesions for which active treatment has not been adopted in time." I have also seen it complicate the various forms of keratitis iritis, sympathetic ophthalmia, and excluded pupil, cataract, dislocated lens, wounded lens, intraocular tumours, ruptured capsule, and extreme myopia.

Of primary glaucoma you will meet with two principal varieties—the simple and the inflammatory. The patient we have just left in the ophthalmoscope room, who is fifty-four years of age, and both of whose eyes are affected, is quite a typical example of the former condition. His wife tells us that he has destroyed his sight by using too strong magnifying glasses, and that his vision varies, being worst at night, worse at some times in the day than at others, and worse on some days than on others. He is a big-framed man, with a full hard pulse, and complains of attacks of dimness of vision, similar to what would be caused by clouds of smoke or fog, with a rainbow round luminous objects. He is subject to headache; the iris is sluggish, and the cornea insensitive. The general acuity of vision is distinctly lessened, amounting to slight short sight; but the peripheral portions of the retina have suffered most, specially, as we ascertained by lamplight (which is best for this purpose), to the inner or nasal side. On ophthalmoscopic examination we found that the optic disc is what is termed cupped, or rather excavated, for it is hollowed out at the sides with overhanging edges, and the pressure which has driven back the papilla has also detached the choroid, so that the disc is surrounded by a whitish ring of exposed sclera. We have ascertained that this is a true excavation and no optical delusion by the parallax, with both the direct and indirect methods of examination, and we have also calculated its depth by reducing to millimetres the different values of the lens required to see the base of the cup and the surface of the retina. "But," you may say, "granting that there is a cup, how do I know that it is a glaucomatous, and not a physiological or congenital cup, or the result of atrophy from absorption of nerve tissue consecutive to cerebral change?" Well, I know that it is a glaucomatous and not a physiological cup, because the physiological cup affects both eyes alike, and in this case the right eye is much the worst of the two. This cup, moreover, occupies the entire area of the papilla, and, most characteristic feature, the vessels are crowded to the nasal side; whereas the physiological cup, however steep it may be, never involves the whole of the disc, and there is no like tucking under, lateral displacement, or changed calibre of retinal vessels. I know this is not a case of simple atrophy, absorption of nerve tissue, or amblyopia from cerebral change, because, apart from other important symptoms, the destruction of the field of vision in cases of atrophy begins on the temporal, and not—as in glaucoma cases—on the nasal side. I know also this is the result of increased tension, because, although there is no spontaneous pulsation of retinal vessels, throbbing is easily induced, as you saw, by the slightest touch on the surface of the eyeball, the artery beating in the centre of the disc and the veins collapsing in concert at its periphery. For the rest, strange to say, the eye looks fairly natural; is not inflamed or congested; nor are the episcleral veins notably enlarged; nor is tension, just now at any rate, very greatly increased. Let us consider what is the cause of these curious symptoms; and first, as to his wife's suspicions. There is no reason to believe that he has been using too strong glasses, for the fact is, the man's accommodation is paralysed from pressure on the ciliary nerves, and strong glasses are a necessity, if he is to see small objects at all. Indeed, you may always suspect glaucoma when a patient is constantly changing his glasses. His vision is worst at night, and varies from day to day, because of slight exacerbations, and because the eye sympathises with fatigue and the general constitutional condition; the clouds of smoke and rainbows are caused by œdema of the corneal epithelium from infiltration with intraocular fluids (Fuchs); the cornea is anæsthetic from pressure on the ciliary nerves as they pass along the inner surface of the sclerotic, and the whole visual acuity is diminished from this cause, as well as from retarded blood supply, the inner or nasal side suffering most, because the vessels supplying the corresponding outer half of the retina have the longest course to run, and are consequently most exposed to pressure. The optic disc is hollowed out because it is the weakest part of the sclerotic, and is therefore the first to give way; the artery pulsates because the intraocular pressure is so great that the blood can only pass at the moment of the heart's contraction; and the fact that all this takes place without any marked hardening of the globe is a proof, either that slight tension long continued will cause grave intraocular changes, or that in this case it has been effected during exacerbations, which are such a distinct feature in almost all forms of glaucoma.

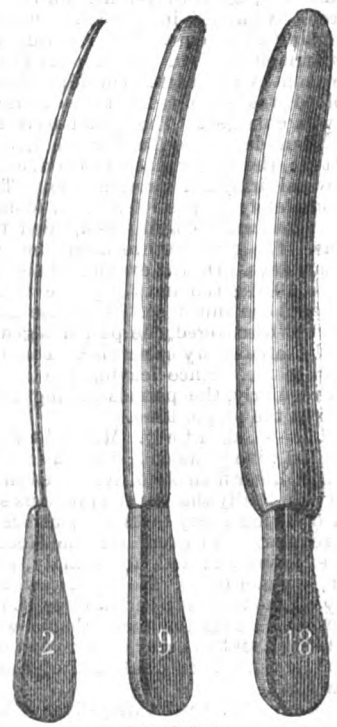
Inflammatory glaucoma, of which you have seen many examples, may prove so intense as to destroy sight in twenty-four hours—hence called *fulminans*. It may resist all treatment, including iridectomy; in fact, get worse whatever you may do—hence called *malignant;* and short of these aggravated conditions, which fortunately are rare, it may occur in a chronic or acute form. The female patient with the green eye (γλαυκον ομμα) *glaucon omma*, to whose case I directed your attention at the commencement of this lecture, is a good example of acute glaucoma. She is fifty-six years of age, has recently lost her husband, and had troubles of various kinds. Six weeks ago she went to bed as well as usual, but was roused in the middle of the night by a violent pain in the right eye, which was swollen, inflamed, and watering freely. She was treated by a local practitioner, but the disease progressed steadily from bad to worse, until at last all perception of light was gone. At present you see that the iris has lost its tint and lustre; that the cornea is dull and anæsthetic; that the eye is as hard as a stone, and that the widely dilated pupil presents a peculiar tint, compounded of a yellow lens and turbid blue aqueous humour. In these cases the disc is not usually cupped, simply because the pressure has not lasted long enough to induce that change. If, however, the fundus can be illuminated, you will see the artery throbbing without any superadded pressure; or, if nothing else is to be seen, the optic disc looming through the turbid vitreous like the sun in a fog. As the disease advances, the iris loses its colour; the pupil dilates, assumes an ovoid form, and is insensible to light; the vitreous and aqueous humour become more or less opaque, and the former has usually so pushed forward the lens and iris base that the anterior chamber is wellnigh obliterated. The patient's sufferings in some cases are little short of agony; in others fever runs high and vomiting is frequent. With many pain is referred to other parts, so that the eye, as the *fons et origo mali*, is apt to be overlooked, and the attendant misled as to the nature of the case. I was once called to a patient whom I found on her hands and knees groaning with her face buried in the pillow. The case had been diagnosed as severe migraine, and six teeth extracted in the hope of relief. Another had had her head shaved and been bled and blistered, on the ground that she was suffering from meningitis; and a third was reported as affected with gastric fever. Iridectomy acted like magic so far as the relief of pain was concerned in each of these cases, but was too late to restore sight in the first two, and was only partially successful in the third. Chronic, inflammatory, and irritable glaucoma present the same symptoms as the acute, but to a less degree; and these forms of the disease, like simple glaucoma, are also characterised by marked exacerbations and remissions.

With regard to treatment. The indications in secondary, consecutive, and traumatic glaucoma are clear enough. We must, whenever possible, remove the cause of disaster.

Digitized by Google

A broken-up lens that blocks the angle of the chamber or presses upon the iris must be let out; the dislocated lens must be extracted, and tension after capsular operations treated by paracentesis. Adhesions with ulceration require iridectomy; and the same operation must be performed whenever glaucoma complicates iritis, irido-choroiditis, and excluded pupil. As to cases of simple and inflammatory glaucoma, it has been very generally taught that all the resources of the Pharmacopœia are powerless to cope with these maladies—an assertion hardly, however, in accordance with facts; for just as a sudden fright, probably by dilating the pupil, may cause or precipitate an attack of glaucoma, so will eserine, by inducing an opposite condition, avert it. Just as anxiety and prolonged vigils may cause increased tension, so will morphia or other hypnotic, if it ensure profound sleep, abort it. Just as a rise in blood pressure from excitement and derangement of the sympathetic and fifth nerve may provoke excessive secretion, so will medication, such as blood-letting, ice, or hot fomentations, elaterine, eserine, pilocarpine, and large doses of quinine (10 grains, Mittendorf), tend to stave off an attack or mitigate its severity. I do not say that such remedies will avail in a severe case, cure or prevent recurrence in slighter ones, or avert gradual deterioration of sight in any; but there is no doubt that the disease may be kept at bay for a time by judicious medication, and it would be unwise to ignore the value of such remedies when from any cause operation is postponed.

(To be concluded.)



ON RAPID DILATATION OF THE CERVIX UTERI.[1]

BY A. H. N. LEWERS, M.D., M.R.C.P. LOND.,
ASSISTANT OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

THE object of the present paper is to draw attention to the safety and other advantages of the rapid method of dilatation of the cervix by means of Hegar's dilators, as contrasted with that of dilatation by tents. Although this rapid method is familiar to gynæcologists, it is not by any means so generally well known as it deserves to be—probably because these dilators are not figured in any of the works on diseases of women commonly used in this country; and I think it may be said that when the necessity for dilating the cervix arises most practitioners still rely on the older method—slow dilatation by means of some form of tent. The disadvantages and dangers of tents are, however, so serious, that I think anyone who will give the rapid method a fair trial will be inclined to abandon the use of tents altogether. Dilatation by tents is not uncommonly followed by more or less severe attacks of pelvic inflammation, peri- or para-metritis, and several deaths from their use have been recorded. Probably, if during the process of preparation all tents were impregnated with a powerful antiseptic, these bad results might be avoided. At present this is not done; and even if it were, we could never be personally satisfied that the particular tents about to be used had been efficiently rendered aseptic by the manufacturer. By using Hegar's dilators any danger of septic poisoning can be entirely avoided.

Hegar's dilators are slightly curved ebonite cylinders about three inches and a half long, the distal end forming a blunt cone and the proximal being fitted with a handle. There are twenty-six sizes usually supplied, the transverse diameter varying from one-twelfth of an inch to one inch. (See Fig. 1.) The method of using them is as follows:—The patient is put in the lithotomy position, and the vagina thoroughly syringed with some efficient antiseptic, such as 1 in 2000 corrosive sublimate solution. Sims's speculum is introduced and the anterior lip of the cervix seized with a pair of vulsellum forceps, preferably a pair having a catch at the handles like Spencer Wells's forceps. The direction of the uterine cavity is then ascertained with an ordinary sound. The dilators should have been previously placed in numerical order in a shallow porcelain tray and covered with a 1 in 20 carbolic lotion. One of the dilators corresponding to the supposed calibre of the cervical canal is then dipped in carbolised oil and passed through the cervix, which is held steady by the vulsellum forceps in the left hand. If the dilator used only passes with difficulty, it is held in position a minute or two before withdrawing it. It is important to have the next larger size ready to pass at once after withdrawing each dilator. In this way the dilators are passed one after the other till the cervix is sufficiently open to admit the finger. This degree of dilatation is usually obtained after No. 19 of the series has passed. If any morbid condition is discovered in the cavity of the body of the

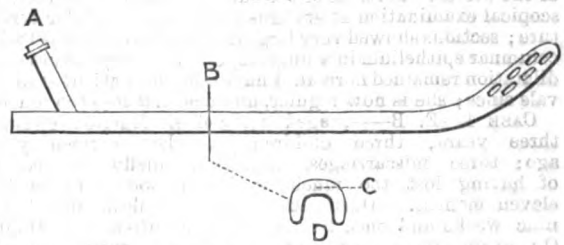


FIG. 1.

Hegar's Dilators.

uterus, this is treated by suitable means. Polypi, for instance, or pieces of placenta can be removed. If a growth of doubtful character is discovered, a small portion may be removed for microscopical examination. Whether anything abnormal has been found in the interior of the uterus or not, it is of great importance to wash out that organ with carbolic lotion or iodine water. For this purpose nothing answers better than the double-channelled tube shown in Fig. 2. No matter how tightly

FIG. 2.

TUBE FOR WASHING OUT THE UTERUS.

The indiarubber tube of an ordinary Higginson's syringe fits on at A. The horseshoe shape of the tube on transverse section at any part (say B) is shown. The fluid injected at A passes between the layers of the tube, as at C. This fluid, after escaping from the holes at the distal end, returns along the groove D, which runs on the under surface of the tube for its whole length.

the tube may be grasped by the uterus, the fluid injected readily escapes along the deep groove on the under surface. These tubes are made of celluloid or glass. Those used in my cases were of celluloid. Subsequently the patient should have antiseptic vaginal douches three times a day for a few days; iodine water is the antiseptic I usually employ for this purpose. If the dilatation is per-

formed soon after a miscarriage, or soon after labour, no anæsthetic is needed, but in other cases it is necessary. The only objection of importance that has been made to the use of Hegar's dilators is, that they are apt to cause deep lacerations of the cervix. I do not think this is an objection of much practical weight. I have used them in a good many cases, and seen them employed in many others without any laceration occurring, and I think this accident must be due to too great force having been employed. In the following seven cases the cervix was dilated with these instruments.

Case 1.—E. S——, aged thirty-nine. Married sixteen years; seven children. Admitted into the London Hospital complaining of losing a large quantity of blood on and off ever since a miscarriage she had five months previously, when about three months pregnant. On admission it was found that some blood was escaping from the external os, and that the uterus was enlarged. The sound passed three inches and a half. Four days later, under ether, the cervix was rapidly dilated: the finger passed into the uterine cavity came on several irregular prominences. These were removed as completely as possible. They looked like pieces of placenta. Pure carbolic acid was applied to the interior of the uterus. The temperature after the dilatation was normal for four days. On the evening of the fifth day there was a rise to 101·4°; the next day the temperature was again normal and continued so. No cause for the rise on that one day was discovered, the patient's general condition being perfectly satisfactory otherwise. Three months later she came to see me. Since leaving the hospital she had menstruated regularly, the periods lasting four days only, and recurring at the proper time.

Case 2.—J. L——, aged forty. Married twenty years; six children, the last nine years ago; four miscarriages, the last before the birth of her fifth child. Admitted into the hospital complaining principally that for the previous six months her periods had occurred every fortnight; before that she had been quite regular. No cause for the bleeding was discovered on examination, and, accordingly, the cervix was dilated rapidly under ether. Nothing, however, was found in the cavity of the uterus to account for the bleeding, and it seemed probable that the menorrhagia was due to the menopause being about to occur earlier than usual. In this case the temperature after dilatation of the cervix never rose above normal.

Case 3.—M. W——, aged thirty-five. Married sixteen years; twins a year after marriage; two miscarriages, the last eleven years and a half ago. Admitted at the hospital on account of menorrhagia of fifteen months' duration. She had been under treatment in the out-patient department, but had obtained no relief. On examination, the uterus was found to be enlarged, and the sound passed four inches. The uterus was freely movable. The vaginal portion of the cervix was healthy. The cervix was rapidly dilated under ether. On passing the finger into the body of the uterus, soft irregular projections, particularly extensive on the right side, were met with. These were thoroughly scraped away with a spoon, and tincture of iodine applied to the interior of the uterus. Portions of the substance removed on microscopical examination afterwards showed a glandular structure; sections showed very large irregular cavities lined with columnar epithelium in a single layer. The temperature after dilatation remained normal. I have seen this patient at intervals since; she is now regular, and does not lose too much.

Case 4.—E. B——, aged forty-five. Married twenty-three years; three children, the last sixteen years ago; three miscarriages. Admitted chiefly on account of having lost too much at her periods for the last eleven months. During this time the flow once lasted nine weeks and once five weeks, and often a fortnight. On examination there was found an erosion on the anterior lip of the cervix; for a time it was thought doubtful whether it was not commencing malignant disease. Under local treatment, however, the erosion improved rapidly, but the menorrhagia was still as bad as ever; the cervix was therefore rapidly dilated. A little sessile lump the size of a split pea was found in the cavity of the uterus near the point of entrance of the right Fallopian tube; it did not admit of removal. The temperature after dilatation remained normal in this case also. This was probably one of the menorrhagic cases commonly met with, apart from local disease, about the time of the menopause.

Case 5.—H. H——, age thirty-seven. Married fifteen years; no children; one miscarriage ten years ago. Admitted complaining of having lost too much at her periods for the last six years, sometimes bleeding for three weeks at a time. The cervix was rapidly dilated till the finger could be passed into the uterine cavity. Nothing abnormal was detected. In this case it is worth noticing that the time occupied in dilating the cervix was only twenty minutes. The patient had had no children, and the external os was small. The temperature on the second day was 100·8° in the evening, but except on that occasion was normal throughout.

Case 6.—G. M——, aged thirty-nine. Married eight years; had one child when she was fifteen years old; none since. Admitted into the hospital complaining of having had a red vaginal discharge for three months. Three months previously she had one of her ordinary menstrual periods, but instead of this passing off in the usual way she continued to have a red discharge till she came to the hospital. In the out-patient department no cause was found for the hæmorrhage, and she was therefore taken in that further investigations might be made. When the anterior lip of the cervix was seized with vulsellum forceps preparatory to dilatation the lip was necessarily somewhat everted, and it was at once evident that there was malignant disease within the cervical canal that had not extended beyond the external os. The cervix was rapidly dilated, and it was found that there was extensive malignant disease in the cervical canal. The cavity of the body of the uterus was healthy. As here we are only concerned with the case so far as it was affected by dilatation of the cervix, I need only say that on the evening of the day when dilatation was performed the temperature was 100·2°; but after that it remained normal.

In the preceding six cases dilatation of the cervix was performed in the non-pregnant condition, in the following case it was done at the sixth month of pregnancy for the purpose of terminating the pregnancy on account of persistent hæmorrhage that was seriously affecting the patient.

Case 7.—Mrs. F——, aged thirty-seven. Married thirteen years; had had four children, the last five years ago; no miscarriages. She was brought to me by Dr. Cockell of Dalston complaining of attacks of pain from time to time across the lower part of the abdomen and back, and of irregular hæmorrhages. Three months before I saw her she had an attack of bleeding lasting five weeks; then she went a month free from bleeding; then it came on again, small clots being passed. The bleeding continued till the time I saw her. The uterus was about the size it reaches at the sixth month of pregnancy. The patient was a good deal pulled down by the bleeding, and it was clearly desirable that the uterus should be emptied as soon as possible. Accordingly the cervix was dilated with Hegar's dilators. As soon as it was sufficiently open to admit of my finger I felt the placenta attached right over the internal os; in fact, it turned out to be a case of placenta prævia. I separated the placenta all round as far as I could reach, and then ruptured the membranes, brought down a leg, and so delivered. The whole period occupied from the time she began to take the anæsthetic till the uterus was emptied was one hour and twenty minutes. Strict antiseptic precautions were used, the vagina being washed out with iodine water before beginning, and the uterus washed out afterwards with the same antiseptic. Two or three injections of ergotin were given hypodermically during the operation. Dr. Cockell wrote to me some time after to say that the case had done extremely well, and that the temperature had never risen above normal. I certainly think that if this case—one of placenta prævia—had been treated by tents instead of the rapid method of dilatation the record would have been a very different one.

PROPOSED COTTAGE HOSPITAL AT ROMFORD.—Early in the year it was resolved to commemorate Her Majesty's Jubilee in the neighbourhood of Romford, Essex, by the establishment of a Cottage Hospital. Tenders for the erection of a hospital capable of accommodating eight patients on a site generously given by a local landowner, W. Mashiter, Esq., have been accepted, and it is hoped that the hospital will be opened before the year closes. The hospital, which is intended to accommodate the residents of the liberty of Havering atte Bow (which includes the parishes of Havering, Hornchurch, and Romford) will cost about £600 for its erection. The committee, of which Mr. A. Wright, M.R.C.S., is treasurer, and Mr. F. Wilson, secretary, have received promises of support to the extent of £850 towards the building and furnishing fund, and £150 as annual subscriptions.

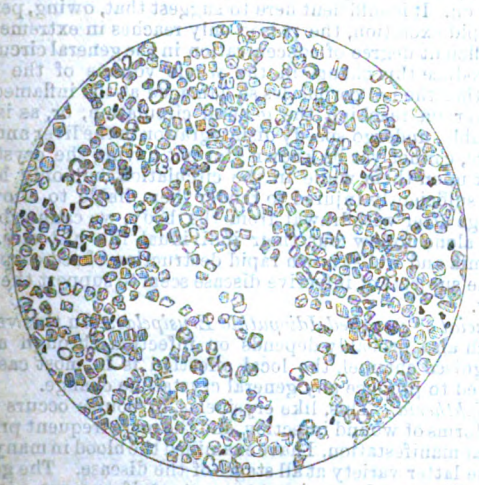
A CONTRIBUTION TO THE PATHOLOGY OF THE BLOOD.

BEING AN ACCOUNT OF CERTAIN CRYSTALLINE CHANGES OCCURRING IN THE HÆMOGLOBIN AFTER WITHDRAWAL FROM THE BODY, IN THE SUBJECTS OF CERTAIN DISEASES, ESPECIALLY THOSE OF SEPTIC ORIGIN.



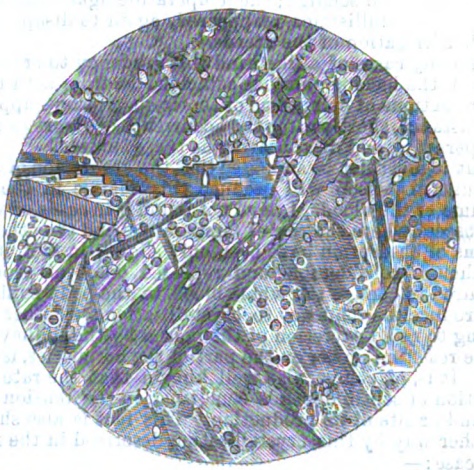
BY C. J. BOND, F.R.C.S.,
SURGEON TO THE LEICESTER INFIRMARY.

PART I.

I MAKE no apology for bringing forward again the well-known subject of crystallisation of the hæmoglobin of the red blood corpuscles; for I think, when viewed in the light about to be described, it is capable of suggesting many useful hints towards the better understanding of the pathology of many diseases, especially those which are associated with the septic processes.

If a drop of normal human blood be drawn from the finger, placed on a slide, and covered with a cover glass, no crystallisation of the hæmoglobin occurs. A ring or cake of dried serum forms around the edge of the cover glass, keeping the blood fluid within for many days; and although some changes occur, such as partial exudation of the hæmoglobin into the serum, there is no crystallisation of the hæmoglobin either in the serum or corpuscles. This is true

FIG. 1.



Normal human blood to which has been added a drop of putrid serum: after twenty-four hours. Shows early stage of crystallisation in septic blood, chiefly in red corpuscles. The ink dots (•) are placed near the corpuscles which show the change best—namely, the ridged, barred appearance, or the flat square plate or crystal form.

of the blood of many of the mammals under like conditions—i.e., the blood of the ox, sheep, dog, cat, mole, rabbit, and guinea-pig: and also in the nucleated blood of birds, frogs, toads, and newts. On the other hand, the blood of the apparently healthy mouse, both wild and tame varieties, shows, under the same conditions, well-marked crystallisation of its hæmoglobin, both in corpuscles and serum, in from twenty to thirty hours. Between these two extremes are many stages, the blood of different animals varying greatly in its tendency to crystallise when withdrawn from the body, that of the same animal varying also according to the healthy or diseased condition it may be in at the time. It is to this crystalline change which human blood undergoes when withdrawn from the body in certain diseases that I wish to draw attention, and especially in those diseases which are associated with the presence in the body of the pathogenic organisms.

At the outset, I would have it clearly understood, that what I maintain, and what I hope to prove, is, not that the blood crystallises in the body in the subjects of septic diseases, but that in certain animals, and in man, under certain conditions of disease, the blood, after withdrawal from the body, shows under the microscope a tendency for its hæmoglobin to undergo exudation and crystallisation, in a period of time varying from twelve hours to several days. Neither do I wish to claim for this phenomenon more importance than it deserves; but value it rather from the way in which, though itself a post-mortem change, it enables us to group together certain diseased conditions, and in these remarks I desire to point out the various diseases in which this crystalline change occurs.

In the first place, as these crystals are somewhat easily overlooked, it may be well to give an example and describe the actual appearances under the microscope. If a drop of blood be taken from the cleansed finger of any patient who is suffering severely from absorption of the products of putrefaction either in a wound or elsewhere, and if such a drop of blood be placed between a slide and cover glass and allowed to remain at the ordinary temperature of the room (60° F.), it will be found that, though it may appear quite normal at the time of withdrawal, after a time varying from twenty to thirty hours, the specimen will show the following changes:—First, the exudation of the hæmoglobin out of the corpuscles into the serum in an area round the margin of the cover glass is in excess of the exudation in normal blood, and gives the serum a marked yellow tinge. Secondly, in a zone just inside this ring or area the corpuscles have lost their spherical or disc-like shape, and have many of them become single, or several crystals of hæmoglobin, and show the prismatic or needle shape peculiar to those crystals; while in some few corpuscles the inside of the corpuscle has apparently crystallised, and the little bars or

FIG. 2.

Normal human blood to which has been added a drop of putrid serum: after two days. Shows later stage of crystallisation which has occurred in the hæmoglobin dissolved in the serum.

needles can be plainly seen inside and apparently distinct from the enclosing stroma. Further, in a marked case the crystallisation will have proceeded further, and have occurred in the form of long parallelograms or needles in the area of exudation mentioned above. In fact, the amount of exudation and the fulness of crystallisation are in proportion to the severity of the symptoms—that is, to the amount of poison absorbed. In a very slight case there is no apparent change; in one in which absorption is more complete or prolonged over a longer time there is slight excess of exudation with crystallisation in a few scattered corpuscles; in a fatal case the whole slide may appear studded with crystals. (See Figs. 1 and 2.) Now since this change does not show itself while the blood is still in the circulation, we can only call it a tendency existing in the circulating blood of patients who are the subjects of certain diseases to undergo, after withdrawal from the body, a peculiar crystalline change, a tendency which is not so shown by the blood of healthy persons. For several years I have examined the blood of many hundreds of patients in this simple way with reference only, or chiefly, to this point of crystallisation, noting down what occurred and the condition of the patient. I propose firstly to give in an abstract form, the result of this examination, grouping the cases under the several heads of the different diseases; and then

Digitized by Google

to offer some remarks on the nature of the change that the blood undergoes.

Sapræmia or Septic Intoxication.—In this affection the symptoms—rigors, high temperature, sickness, diarrhœa, headache, or delirium—are due to the presence in the circulation of an unorganised substance, the product of decomposition, and associated with the life history of the organisms of putrefaction, the poison itself being called by various names—sepsin, zymin, &c. In severe cases the crystalline change is well marked. It varies, moreover, in direct proportion to the amount of poison absorbed, and to the interval elapsing between its introduction and the withdrawal and examination of the drop of blood. The following case illustrates these points:—

A patient was suffering from decomposition of a retained placenta, having a temperature of 106° on the second day after delivery, a pulse of 150, rigors, delirium, pain in the bones, and diarrhœa. The blood at this time, examined by Koch's method, showed no organisms whatever, but after remaining on the slide sixteen hours, marked crystallisation of the red corpuscles could be seen. The placenta was removed under $CH.Cl_3$, and the uterus thoroughly washed out with carbolic acid lotion. On the following morning—that is, in about twenty hours after the removal of the placenta—the temperature was normal and the pulse 100, the patient being almost convalescent. The blood now showed no tendency to crystallise at all, proving that, the source of the poison having been removed, and that already in the circulation having been excreted or destroyed, the blood had regained its normal condition in less than twenty-four hours. But, further, in two days' time slight decomposition again occurred in the uterine discharge; the temperature again rose to 102°, and the crystallisation reappeared, again to disappear on a further irrigation of the uterus.

In many cases of a like kind this tendency to crystallisation of the hæmoglobin has coincided in time with marked exacerbations of symptoms of septic absorption—appearing, for instance, shortly after the occurrence of rigors or rises of temperature, and disappearing as these subside.

But it must not be supposed that the absorption of a small amount of poison will produce this change in the whole volume of the blood. I have not found it in cases of wounds or abscess where the rise of temperature and the other symptoms of absorption have been only slight; in fact, it seems as though considerable and repeated doses of sepsin are required to change the whole blood in the body sufficiently to produce the tendency to crystallisation: whether this be owing to rapid excretion of the poison by the kidneys, or to some resisting power on the part of the corpuscles, is doubtful. It is, of course, also well known that the rate of absorption of sepsin depends somewhat on the tension in the wound or site of its production. This fact is also shown in another way by this crystallisation described in the following case:—

The blood was examined from the finger of a patient with a feculent abscess in a neglected and inflamed hernial sac. It showed marked crystallisation in forty-eight hours. A free incision was made, and the pus let out. Sixty hours afterwards, the tension having disappeared, although the cavity continued to discharge a quantity of most offensive pus, the crystallisation could no longer be detected.

The Septic Infective Diseases: Septicæmia and Pyæmia.—I have examined the blood repeatedly in many cases of septicæmia and pyæmia—in cases which have and in those which have not been accompanied with abscesses in the internal organs, with suppuration of joints, and with secondary localised inflammation of the connective tissues. The crystalline tendency does not seem so constant or in such direct proportion to the severity of the symptoms at the time as in the case of sapræmia or septic intoxication, although it is present in most cases of septicæmia, and in nearly all fatal cases towards the end of the disease. It varies, too, in the extent of the crystallisation and in the length of time the blood must stand on the slide after withdrawal before it appears, from day to day of the illness, and seems to have more connexion with the amount of poison absorbed at each separate septic focus than with the number or position of the abscesses. It appears, in fact, to depend not so much on the presence of the organisms in the blood as on the chemical products of their growth, and this view will receive further confirmation when we speak of anthrax.

Erysipelas and Erysipelatous Inflammation of Cellular Tissue.—In slight cases of this affection, where the local affection is not very extensive and the constitutional symptoms slight, the general blood, or that from the general circulation, shows no change. When, however, there is marked constitutional disturbance, the crystallisation appears in from twenty-four to forty-eight hours after withdrawal. But it was in the case of erysipelas that a difference was first noticed according to the site from which the blood was taken. Thus in the case of a man with marked erysipelatous cellulitis of hand and forearm without suppuration, the temperature being 104°, blood taken from the margin of the inflamed area crystallised fully in twenty-four hours, whereas a drop taken from the finger of the other hand only did so very partially after forty-eight hours. Also in a case of so-called "perambulating" erysipelas, in which the erysipelatous wave started from the breast and travelled over the greater part of the body, blood taken from the red inflammatory area about four inches wide crystallised well, while that taken from the healthy skin in front of the wave and from the tissue which had recovered after the wave had passed over it, showed little or no change. Thus we see that blood taken from a part of the body which is the site of an inflammation of an infective character shows a tendency to undergo crystalline degeneration, whereas the general blood of the body in such a case only does so after long and repeated constitutional infection. We must remember not only that the poison, whatever it be, is manufactured at this area, but that in addition, owing to the extreme local vascular congestion, the blood is more or less stagnant here and lies long in contact with the inflamed tissues, and perhaps also with the organisms themselves; but this point will receive further consideration later on. It is sufficient here to suggest that, owing, perhaps, to rapid excretion, the poison only reaches in extreme cases a sufficient degree of concentration in the general circulation to produce this change in the whole volume of the blood. Whether the red corpuscles so damaged at the inflamed area recover on reaching the general circulation, or, as is more probable, undergo speedy disintegration in the liver and elsewhere, cannot yet be known; for not having the crystalline mark upon them while in the circulation, but only having been sufficiently injured to render them liable to show this change after withdrawal from the body, we cannot by this sign alone follow out their individual life histories. The anæmia and well-known rapid destruction of red corpuscles in the subjects of infective disease seem to support the latter view.

Facial or so-called Idiopathic Erysipelas.—In this variety, which also probably depends on infection through an unrecognised channel, the local affection is in most cases too limited to produce any general crystalline change.

Diphtheria.—This, like erysipelas, of course occurs in the two forms of wound infection, and the more frequent primary throat manifestation. I have examined the blood in many cases of the latter variety at all stages of the disease. The general crystalline tendency is not constant if present; it only occurs after the blood has remained on the slide from forty-eight hours to three or four days, and appears to bear some slight relation to the amount of constitutional infection, and very little to the local symptoms.

Typhoid Fever.—In all the uncomplicated cases of typhoid in which I have examined the blood—that is, cases arising in previously healthy persons, and uncomplicated with pneumonia, bedsores, abscesses, &c.,—the crystalline blood change has never been detected. This is somewhat remarkable when we remember that typhoid fever, like diphtheria and erysipelas, is a specific disease having a local manifestation in the intestines and constitutional effects, as seen in the rash, &c.; in this it resembles measles, scarlet fever, and small-pox, and it is interesting to note that, as in typhoid fever, so too the crystalline change is also absent in uncomplicated cases of *measles*, *scarlet fever*, and *small-pox*. *Typhus* I have not had an opportunity of examining. With regard to this latter group of diseases—diphtheria, typhoid, measles, and scarlet fever,—there are one or two interesting points which need further remark. They are more or less protective (that is, one attack confers immunity from a second) in a gradually increasing degree as we ascend the series: diphtheria least so; scarlet fever most so. Also diphtheria is perhaps the most local, and scarlet fever the most general or constitutional in its manifestation. And, as if to correspond to this, diphtheria at one end of the series shows the crystalline blood change slightly, while it is absent in the other diseases. What is the exact meaning of this association we are not yet able to say.

Digitized by Google

Anthrax, or Splenic Fever.—This is, perhaps, the one example of a disease having an infective origin of which the pathology or life history is fully known. First, in animals. In guinea-pigs, although the blood readily crystallises when treated in certain ways, it never does so when normal blood is placed on a slide in the manner described above; it does, however, crystallise on the slide if the animal be suffering from, for instance, a septic peritonitis, thus showing that the change is a test of some value in the case of these animals. A guinea-pig was inoculated subcutaneously with anthrax spores; in forty-eight hours it died, with marked symptoms of splenic fever. The blood examined at various stages of the disease was crowded with the bacilli, but showed no tendency to crystallise on the slide either in the corpuscles or in the hæmoglobin that had exuded into the serum.

In the case of a veterinary surgeon who became inoculated while making a post-mortem on a cow, dead of splenic fever, a well-marked characteristic malignant pustule appeared at the site of inoculation on the wrist. Examination of the discharge from this showed great numbers of the bacillus anthracis; the patient recovered after energetic injection round the pustule of pure carbolic acid. The general blood was examined before and during treatment; no bacilli were detected in it, and it never showed any crystalline tendency.

This was a case of so-called external anthrax or malignant pustule, in which the constitutional infection was very slight, and the influence of the organisms or the absorption of poison at the site of inoculation insufficient to produce a crystalline change in the whole volume of the blood. A distinction must be drawn between these cases and those of internal anthrax, in which the spores are received into the lungs; in these cases the constitutional effects appear to be more marked, and I have not been able to examine the blood in them. Judging, however, from the facts in animals, it would seem that anthrax ought really to be looked upon as a mycosis; that death is brought about by the invasion and plugging of the capillaries and lymphatics of the host by the thousands of bacilli, and not by the manufacture of any chemical poison, and this view receives some confirmation from the absence of the crystalline change in the blood in this disease.

Pneumonia.—The relationship between this disease and the presence of the organisms first described by Friedländer is now fairly well established. Whatever be the real relationship, however, whether the high temperature, &c., is the result of absorption of chemical products in the affected lung or due to other causes we do not know. In these acute cases the crystalline tendency is not at all constant, it was absent in a well-marked case in a boy with a temperature of 106°, and it only appears in fatal cases just before death or in long-continuing cases attended with breaking down of lung tissue. In the absence of further evidence, I think another cause besides septic absorption will be found to explain the high temperature and constitutional symptoms, and I think the absence of the crystalline change points to this suggestion.

Ague.—I have examined the blood in several well-marked cases of ague in the hæmatial and following stages, and have not noticed any alteration of the corpuscles in the direction of crystallisation. Although ague is known to be caused by the presence of organisms in the system, we do not yet know the pathology of its latency and periodicity. If again the symptoms are due to absorption of chemical products, this is not sufficient in amount, or prolonged enough in time, to affect the whole volume of the blood.

Phthisis.—In this disease the crystalline tendency can generally be detected towards the end of fatal cases. In some acute cases it is, however, absent.

General Tuberculosis.—Two cases were examined, and no change detected.

Cancrum Oris.—Blood taken from the finger in a well-marked case of this emphatically infective process showed marked crystallisation in twenty-four hours.

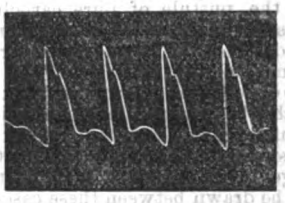
Reviewing, then, this list of so-called infective diseases in which the blood has been examined, we find that the crystalline tendency is most marked in those diseases in which there is commonly the greatest evidence of absorption of chemical products; these are sapræmia, septicæmia, and pyæmia, erysipelas, cancrum oris, and advanced cases of phthisis. In the others it is inconstant or absent, and, as has been pointed out in the case of anthrax, this absence [illegible] the possibility of the constitutional symptoms in these cases being due not merely to chemical absorption, but to some other as yet unknown factor or factors; this applies to such diseases as typhoid, pneumonia, scarlet fever, measles, &c. If we allow ourselves to speculate a little further on a question regarding which the evidence is at present very incomplete—if, for instance, we regard the immunity from subsequent attack conferred by one attack of many of these diseases to be due to the fact that the products or substances evolved and circulating during the first attack have so acted on and changed the blood and tissues as to render them proof against further invasion by the same organisms—then, judging from the foregoing observations, it would appear that it is not the absorption and circulation of the highly differentiated protective product which produces in the blood this crystalline change, for it is absent in scarlet fever, measles, &c.; but that the less differentiated non-protective simple product of putrefaction does so to a marked extent, as in sapræmia, &c., and this points to a marked difference in the products produced by the life and growth of different organisms.

ON A CASE OF CARDIAC DILATATION.

BY GRAHAM STEELL, M.D.,
ASSISTANT PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

IN THE LANCET of Aug. 14th, 1886, I recorded a case of heart disease as an example of that considerable class in which the primary incidence of disease is upon the muscle, and not upon the valves. I am now induced to publish a somewhat similar case, which, however, offers one important difference—namely, the absence of murmur. Although in the former case the murmur disappeared under treatment, and was thus a temporary feature, the importance of the difference referred to is not on that account diminished. The coincidence of the disappearance of the murmur with recovery naturally pointed to regurgitation through the mitral curtains, consequent on defective muscular adaptation, as the cause of the circulatory disturbance. Further, an important, if not the essential, *rôle* in the production of the dilatation of the ventricle may be claimed for the valvular incompetence with some reason. In the case of structural damage of the mitral valves entailing their incompetence, we know how often dilatation of the left ventricle takes place. This is seen especially in the young, in whom there is least likelihood of inherent defect of the heart muscle. The explanation of the dilatation under the circumstances is, probably, that the obstruction to the circulation—namely, the backward flow into the auricle—reacts during the diastole on the ventricle, which then receives an abnormally large amount of blood as the result of the valvular incompetence. The first tendency is to dilatation; only afterwards does hypertrophy become established. In the case now to be described there can be no such explanation of the dilatation, at least if it be granted that mitral incompetence is expressed clinically by murmur. In the full intensity of the disturbance of the circulation we had, I believe, trustworthy evidence of the competence of the mitral valves, yet the circulatory disturbance was the same in both my cases—pulmonary congestion and general venous stasis,—and yielded in precisely similar manner to the same treatment.

It has long been known that there is a form of cardiac dilatation which during life is accompanied by no evidence of valvular incompetence of any kind, and in which the circulatory disturbance is identical with that commonly resulting from valvular incompetence. Before the capacity of the left ventricle is increased, I hold that one of two events has occurred—namely, valvular incompetence or imperfect emptying of the ventricle, the so-called *asystole*, a condition which I shall term *systole catalectic*. Let us take, for example, a simple case of aortic stenosis carried to a considerable degree. It seems to me that no enlargement of the left ventricle will occur so long as two conditions are fulfilled, and these two conditions are (1) that the mitral valves shall remain competent, and (2) that the ventricle shall complete its systole on every occasion. We know that in health the supra-papillary space of the ventricle contains a small quantity of blood at the end of systole, and by a completed systole I only mean the normal emptying of the chamber. Systole catalectic must, I fancy, be a more common result of a failing ventricle than we are wont to



Digitized by Google

believe. Do not the huge rounded ventricles which we so often see on the post-mortem table emphatically teach this? Can we imagine that these huge deformed ventricles have closed in normal fashion for weeks or months before the patient died? To return to aortic stenosis: The obstacle which this lesion opposes to the circulation the ventricle encounters during the systole, and to enable the ventricle to overcome the obstacle increased power in its wall is alone necessary. Hypertrophy—not dilatation—results so long as the conditions that I have named are fulfilled. Their fulfilment, however, implies a well-nourished heart. Should the nutrition of the heart fail, its contractile power inevitably also fails; and whether it be mitral incompetence or systole catalectic, or both, that follows, the ultimate result is the same—dilatation. What has been said of aortic stenosis applies with equal force to the high arterial tension associated with Bright's disease and other states. When there is incompetence of the aortic valves in place of stenosis of the aortic orifice, all the circumstances of the case are altered. The obstacle opposed to the circulation is met by the ventricle during diastole in the first instance. Yet it has to be overcome by the ventricle during systole. The very transference implies a degree of dilatation. From the outset here the tendency is to dilatation, and only later does hypertrophy come, as it were to the rescue.

Both in the case which I formerly published and in that which I now publish failure in the nutrition of the heart muscle seems to have been the first morbid change. In the former mitral incompetence became early established; in the latter systole catalectic supervened, while the mitral curtains closed normally. I am unable to give an explanation of the different effects in the two cases respectively. The general resemblance to Bright's disease of the case to be narrated is very remarkable. It would have been still more so had there been albuminuria, which one cannot regard as other than a likely consequence of the disturbed circulation. Had albuminuria existed, it would in all probability have proved transient. On the other hand, it must be remembered that cardiac failure is a not very rare accident in Bright's disease, and it is then of much importance, in regard to treatment, to recognise the cardiac element in the case. When this combination exists, the characteristic high arterial tension of Bright's disease disappears, and the pulse becomes of low tension, and so resembles the pulse of mitral regurgitation.

T. S——, aged thirty-two, a carter, was admitted into the Manchester Royal Infirmary on July 8th, 1887, having presented himself at the out-patient department on the previous day suffering from dropsy of the lower and upper extremities, and of the trunk and scrotum. Nine weeks before admission he had a fit one morning while at work. His tongue was not bitten, but he believes that he was convulsed. He was quite unconscious for a time. He went back to work the same day, but felt very dizzy. Five weeks before admission he noticed swelling of the lower extremities as high as the thighs, and gave up work. A fortnight later, while going upstairs he became very breathless; but for the last three years his wind has been bad, exertion bringing on shortness of breath. He noticed his arms swollen for the first time on July 7th, and his scrotum only on the day of admission. He has suffered more or less from cough and expectoration for the last ten years. Two years ago he expectorated some blood after coughing severely. Several weeks later he had a sharp attack of epistaxis. With these exceptions his health has been very good. There is no history of syphilis, rheumatic fever, or gout, nor, indeed, of any illness before the occurrence of the fit. His father died at the age of forty-five of heart disease; he had been known to be suffering from the complaint, but died after a quarter of an hour's serious illness. His mother died at the age of thirty-four, but the cause of death is unknown. He had two brothers and a sister, but all three died before the age of twelve; the last was killed by accident, and the cause of death of the brothers is unknown. The patient is a widower, and had six children, but all died within a year of birth except one, who survives, aged fifteen. He is a well-built, strong-looking man, of rather fair and healthy complexion. His lower extremities, trunk, and arms (including hands) are œdematous, and pit on pressure. He can lie upon his back, or upon either side, without discomfort. There is no arcus senilis. There are no tophi on the ears. Temperature in axilla 98·4°. Since the age of fifteen the patient has been in the habit of drinking beer freely. He has taken spirits very seldom. Of late years his daily allowance of beer has amounted to four or five pints. He has no cardiac pain and no dyspnœa while at rest. He has suffered from palpitation after exertion, but there is none at present. The pulse is full, soft and regular (see Chart 1). On inspection of the chest, a slight diffuse pulsation is visible in the fifth space, in and to the left of the nipple line, also in the epigastrium. The impulse is barely perceptible with the hand, being very weak and ill-defined. The external jugulars are distended, and pulsate slightly. The arterial pulsation in the neck is perhaps exaggerated. The heart is ascertained by concussion to be considerably enlarged, both sides taking part in the enlargement. The maximum extent of dulness from the middle line is to the right two inches, to the left five inches and a half. There is no dulness above the third rib. There is no murmur audible in any area. The first sound is somewhat dull and prolonged. The second pulmonary sound is somewhat accentuated. In the mammary line the lower liver border is situated two inches below the costal margin. The total hepatic dulness in the same line measures six inches. A few rhonchi are heard over the lungs generally. Over the base of the right

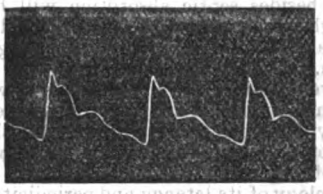


CHART 1.

lung posteriorly there is dulness, loss of vocal fremitus, and diminished breath sound. The chest wall is very œdematous. The urine is of a deep amber colour, acid, and deposits lithates; sp. gr. 1021. Not a trace of albumen can be discovered by any of the following tests: cold nitric acid, boiling picric acid, and the acid saline solution.

July 11th: Pulse 84; respiration 24. Complains of having no use in his legs, but has complete power of movement of them. He is very breathless when he gets out of bed. Thick lithate deposit in the urine, which contains no albumen. Yesterday he began taking the following mixture: infusion of digitalis, 4½ oz.; tincture of squills, 3 dr.; infusion of senega, 12 oz.: one fluid ounce three times a day. Dulness at the base of the right lung less; fremitus perceptible; fine crackling sound with inspiration over dull area.—12th: To have 5 grains of calomel to-night.—13th: Digitalis mixture to be taken only twice daily.—14th: Urine less deep in colour, and does not deposit lithates.—17th: To have only one dose of digitalis to-day. Legs still œdematous; lower part of the back very œdematous; passing more

CHART 2

urine.—18th: Two doses of digitalis.—19th: One dose in the morning.—20th: Digitalis stopped. Dropsy practically gone; no pitting on pressure anywhere; feels quite well except in legs, which are somewhat stiff down the backs; tongue clean and moist. Respiration 28; pulse 72. A few rhonchi are audible over the chest, and there is a little frothy mucous expectoration. Ordered the following mixture: tincture of nux vomica and tincture of perchloride of iron, of each 2 dr.; water to 12 oz.: one fluid ounce three times a day, also a cough mixture, if the cough is troublesome. At the apex of the heart the sounds are deficient in tone, but there is no murmur either here or at the base. Since the last report the aortic second sound has gained much in intensity, while the pulmonary second sound has diminished in intensity. The lower border of the liver is now situated in the mammary line barely an inch below the ribs. A sphygmogram taken to-day shows a very decided increase of vascular tension. (It closely resembled the tracing taken on the 23rd, and appended.)—23rd: Sphygmogram taken to-day (see Chart 2).—24th: Patient allowed to get up to-day. He is quite convalescent.—28th: Percussion

Digitized by Google

of the heart to-day shows a decided diminution of dulness to the right of the middle line, and it now extends only one inch from mid-sternum in that direction. The dulness to the left remains unchanged. The general condition of the patient is excellent.

The following is the record of the daily quantity of urine passed:— July 9th, 13 oz. (digitalis commenced); 10th, 10 (?) oz.; 11th, 22 oz.; 12th, 24 oz. (calomel, 5 grs.); 13th, 20 oz.; 14th, 52 oz.; 15th, 63 oz.; 16th, 54 oz.; 17th, 78 oz.; 18th, 88 oz.; 19th, 110 oz.; 20th, 70 oz. (digitalis stopped); 21st, 70 oz.; 22nd, 64 oz.; 23rd, 66 oz.; 26th, 55 oz.; 27th, 48 oz.

STROPHANTHUS AS A HEART TONIC AND DIURETIC.

BY WM. BUDD, M.D. BRUX., &c.

IT is notorious that there is no class of drugs so uncertain in their action as diuretics, and the physician is often perplexed and disappointed by the failure of one drug after another to increase the amount of fluid secreted by the kidney, and to relieve his waterlogged patient. Through the important researches, however, of Professor Fraser, we have a heart tonic and diuretic at our command which I think is likely to prove far more valuable in suitable cases than digitalis, caffeine, &c.; and it has the double advantage over digitalis that it is not cumulative. I trust that the record of the following two cases, in which the great benefit produced seemed to be the result of the administration of the drug in question, may not be without interest to the profession.

CASE 1. *Morbus cordis; emphysema; œdema pulmonum.*—H. B——, aged sixty-seven, came under my care on March 23rd. Has never had acute rheumatism. Has a mitral systolic bruit, most audible at the apex of the heart, hyper-resonance on percussion, generally over the chest, with prolonged expiratory murmur and minute crepitation at the bases of both lungs. The urine was slightly albuminous and very scanty, of specific gravity 1020, and no casts; pulse 92, feeble and irregular. The amount of urine secreted was scarcely eight ounces a day, and there was considerable anasarca. My treatment consisted in the administration of hydrogogue purgatives, such as compound jalap powder, and various diuretics, such as carbonate of potash, squills, digitalis, and blue pill, but without any marked increase in the amount of urine. At this time orthopnœa was very distressing, and the patient was obliged to sit upright in an armchair night after night. On April 26th the urine was so scanty that it could not be collected for measurement, and the anasarca was rapidly increasing, and the crepitation over the bases of the lungs had considerably extended. The patient's face was livid and extremities cold (pulse 100, feeble and irregular), and he was evidently in a critical condition. I then ordered five minims of tincture of strophanthus to be taken three times a day. On April 28th I was pleased to find the condition of my patient much improved, his pulse was considerably stronger and quite regular, and the quantity of urine began to increase, and amounted to thirty-five ounces in the twenty hours. There was also a marked amelioration in all his symptoms. I had the urine collected as detailed in the subjoined table:—

April	30th	... ...	35 oz.	May	16th	... ...	80 oz.
May	1st	... ...	46 „	„	17th	... ...	84 „
„	2nd	... ...	52 „	„	18th	... ...	80 „
„	3rd	... ...	64 „	„	19th	... ...	76 „
„	4th	... ...	65 „	„	20th	... ...	80 „
„	5th	... ...	85 „	„	21st	... ...	80 „
„	6th	... ...	99 „	„	22nd	... ...	74 „
„	7th	... ...	95 „	„	23rd	... ...	76 „
„	8th	... ...	106 „	„	24th	... ...	78 „
„	9th	... ...	105 „	„	25th	... ...	90 „
„	10th	... ...	104 „	„	26th	... ...	90 „
„	11th	... ...	104 „	„	27th	... ...	80 „
„	12th	... ...	105 „	„	28th	... ...	65 „
„	13th	... ...	100 „	„	29th	... ...	75 „
„	14th	... ...	83 „	„	30th	... ...	75 „
„	15th	... ...	85 „	„	31st	... ...	72 „

On May 18th I noted that the œdema had disappeared to a great extent, and that of the lungs had entirely cleared up, air passing freely into the lungs. On the 22nd I gave the strophanthus twice daily only, and thirty grains of compound jalap powder every other night. On May 30th it was noted that the anasarca had absolutely disappeared. On June 16th the patient was free from dropsy and from œdema of lungs, and expressed himself as feeling very well.

CASE 2. *Morbus cordis; albuminuria; ascitis; anasarca.*—F. W——, aged forty-one, married and the mother of five children, came under my care on March 12th. There was a loud systolic bruit at the apex of the heart, the impulse of which was very much increased; the pulse was very small, and both irregular and intermittent. The liver was also considerably enlarged, extending two inches below the margin of the ribs, and there was a certain amount of ascitic fluid in the peritoneal cavity. Urine contained one-third albumen; specific gravity 1015. I could detect no casts under the microscope. She stated that considerable œdema of the legs had existed for many weeks. I ordered her tartrate of iron, with squill and digitalis, and also to drink lemonade made with acid tartrate of potash, and compound jalap powder every other night. The urine was very scanty, and very little improvement took place. On March 23rd I ordered five minims of tincture of strophanthus three times a day, and continued the compound jalap powder every other night. On March 25th the pulse was stronger and more regular; the urine by measure was found to be 16 oz., and increased in amount daily, as will be seen below.

March	26th	... ...	20 oz.	April	10th	... ...	68 oz.
„	27th	... ...	20 „	„	11th	... ...	80 „
„	28th	... ...	30 „	„	12th	... ...	56 „
„	29th	... ...	35 „	„	13th	... ...	48 „
„	30th	... ...	40 „	„	14th	... ...	45 „
„	31st	... ...	56 „	„	15th	... ...	48 „
April	1st	... ...	55 „	„	16th	... ...	46 „
„	2nd	... ...	58 „	„	17th	... ...	49 „
„	3rd	... ...	56 „	„	18th	... ...	50 „
„	4th	... ...	60 „	„	19th	... ...	54 „
„	5th	... ...	72 „	„	20th	... ...	50 „
„	6th	... ...	78 „	„	21st	... ...	42 „
„	7th	... ...	65 „	„	22nd	... ...	36 „
„	8th	... ...	76 „	„	23rd	... ...	42 „
„	9th	... ...	65 „				

On April 14th I noted that there was only a trace of albumen present, and also that the œdema of the legs was much reduced, as was also the amount of ascitis. On April 30th she was quite free from either œdema or ascitis, and she expressed herself as feeling as well as she had been for years.

Remarks.—I think these two cases show the undoubted beneficial effect of strophanthus after the failure of digitalis, &c. Its great advantages over the latter drug are that no cumulative effect was observed even after it had been given for several weeks continuously, nor was there any gastro-intestinal disturbance, which is so frequently produced by digitalis; and in disturbances of the circulation, when the blood-pressure is low, strophanthus is capable of producing a marked diuretic effect.

Exeter.

ON A CASE OF EMPYEMA.

BY ANDREW DUNLOP, M.D.,

CONSULTING PHYSICIAN TO THE JERSEY GENERAL DISPENSARY AND INFIRMARY.

ON the evening of March 3rd, 1886, I was called to see A. B——, male, aged seventeen. I found him suffering from pain in the right mammary region; he had cough, and he was spitting up somewhat tenacious mucus coloured nearly throughout with bright-red blood. There were no definite physical signs, the temperature was 102°, the appetite was poor, and the bowels were regular. The history given was that while in the enjoyment of good health he was exposed to cold on the night of March 1st, and that he began to suffer from malaise next day. On the morning of the 3rd he had distinct rigors and began to suffer from pain in the right side. During the day he seemed to get worse, and I was sent for. On the 4th signs of pneumonia began to show themselves at the right base, and next day they were fully

Digitized by Google

developed, along with some indications of pleuritic effusion. During the first ten days of his illness the morning temperature ranged between 100° and 102°, and that of the evening between 102·4° and 103·8°. The pulse was good, its rate never being above 108. The respiration sometimes reached 60, but the patient was never distressed with dyspnœa. There was almost constant, and sometimes severe, pain in the right side, and there were profuse perspirations. At first the pneumonic symptoms and signs predominated, but soon they began to subside, and those of the pleuritic effusion gradually occupied the first place in importance. On the 12th the temperature fell to normal, and by this time nearly all blood had disappeared from the expectoration, and there was much less pain in the side. The effusion, however, had increased, and there was now absolute dulness all over the back, except, perhaps, in the supra-spinous fossa, and in front the dulness reached as high as the upper border of the fourth rib when the patient sat up. After this, everything went well for a time. The temperature kept normal, the respirations gradually fell from 36 to 34, the pulse kept at about 96, and there were indications of commencing reabsorption of the fluid. The patient began to sit up a little every day, he had little cough, his breathing was easy, and he felt that he was gradually improving. On the 22nd, however, he began to complain of severe pain on the right side, and his temperature rose again. Between this date and the end of the month the effusion gradually increased, until there was complete dulness all over the right side, except under the clavicle, where there was a well-marked tympanitic note. A similar note was produced all along the right border of the sternum, extending about an inch outwards. The temperature kept about 101°, and the pain in the right mammary region was severe, but the respiration did not rise above 34, and there was almost no dyspnœa. During the first week of April the right pleural cavity became completely filled, the liver was depressed, and the patient suffered from piles. The heart was pushed to the left, and the right side measured about an inch more than the left. The temperature, however, sank to normal, and the respirations were only from 25 to 30. On April 8th I aspirated in the fifth space, a little behind the mammary line, but I could only succeed in withdrawing about half an ounce of fluid, the aspirator getting constantly blocked with shreds of flocculent matter. The fluid withdrawn, however, was pus, of a bright-yellow colour, and free from odour. On the 10th I aspirated again, this time in the fourth space, just in front of the anterior axillary line, and withdrew about twenty ounces of inodorous pus. Dr. le Rossignol, who saw the patient with me, agreed that the best course would now be to wait for a few days and watch the effect of the aspiration; then, if the pus reaccumulated rapidly, to diminish it by a second aspiration, and a day or two later to make a free incision. After the aspiration there was a somewhat tympanitic percussion note all over the front, with good respiration in the subclavian region; behind, the chest was dull all over, with only a little faint respiration audible. The temperature was normal (after this it never rose, except once, to 99·5°), the pulse was 120, and the respiration 24. By the 15th the chest had filled up again to a considerable extent, there being dulness in front as high as the upper border of the third rib. It was noticed about this time that the finger tips, which had been gradually enlarging, had become very distinctly clubbed. On the 16th an attempt was made to aspirate, but owing to the blocking of the tube very little was drawn off. On the 19th, with the kind assistance of Dr. le Rossignol and Mr. Hind, chloroform was administered, and an incision was made between the sixth and seventh ribs, beginning just behind the anterior axillary line, and extending forward for about a little more than two inches. A free opening was made into the pleural cavity, and two fingers were passed into it to stem the torrent of pus, which escaped in large quantity. Antiseptic precautions were taken, but no spray was used. After the pus had ceased to flow freely, an indiarubber drainage tube, about three inches long and pretty nearly half an inch in diameter, was passed into the chest. This tube was attached to a broad indiarubber chest piece, under which was placed a piece of protective, and under this again, next the wound, a piece of lint soaked in carbolic oil. Over the whole was placed a thick pad of salicylic wool, which was kept in position by means of a broad binder. The dressing was changed in the evening, the tube being taken out, washed, and replaced. The wool was found saturated with pus. By the 23rd the discharge had diminished very greatly. At first, at each change of dressing, night and morning, the wool was found saturated with pus, but now there was only about two or three ounces. Each time the dressing was changed the tube was taken out and thoroughly cleansed. Latterly a fold or two of carbolic gauze had been placed over the chest piece and orifice of the tube, as the wool was found to block it and to get into the wound. I had also begun to change the dressing under carbolic spray. The temperature had never risen since the operation, and the patient was comfortable. In the course of another week there was little discharge except when the patient sat up, and then there was a free rush, sometimes apparently amounting to about a pint. This gradually lessened, and towards the middle of May, when he had begun to sit up a little each day, there was only an ounce or so of discharge when he first got out of bed. The dressing was now only changed once a day, and the tube had been more than once replaced by a shorter one of lesser diameter. He ate well and gained flesh rapidly, and the digital clubbing began to diminish. The chest wall on the affected side had fallen in a good deal, the sinking being especially marked under the clavicle, and the liver had risen quite up to, if not above, the level of the incision. The percussion note was good, though rather tympanitic in quality all over the front; it was fair down the back to the base, where it was dull, and there was a dome-shaped area of dulness in the lower axillary region. Somewhat weak respiration was heard all over the front; still weaker breathing was heard over the upper two-thirds behind; but the breath sounds were quite inaudible over the dull areas at the base and in the infra-axillary region. At the beginning of June there was only a spot or two of pus on the dressings, with a little watery discharge; sometimes the wool was quite clean. The breathing was now better heard, and the patient was moving about a little. On June 5th the tube was removed, and the wound healed up completely almost at once. On July 18th I made the following note of his condition: "Has gained flesh considerably. Little digital clubbing. Considerable re-expansion of the right chest has taken place, but it is still contracted, especially under the clavicle; the right nipple is lower than the left. Under the nipples the right side measures about a quarter of an inch less than the left. The expansion on breathing is three-quarters of an inch on the right side and one inch on the left. The right side is resonant all over, the percussion note being a little tympanitic in front. Good breathing is heard all over the front, and somewhat weaker breathing over the upper three-fourths of the lung behind. The respiration is still weaker at the base, and is only faintly audible in the lower axillary region. The wound has evidently been long thoroughly healed. Very slight lateral curvature of the spine, the concavity to the right. In good health and can do a fair amount of exercise. He notices, however, that he perspires easily." On Nov. 2nd I saw him again, when the following note was made: "Has grown stout and strong. Little deformity of chest. Right side a quarter of an inch less than left; right nipple lower than left. The breathing heard over the front of the right side is equal to that on the left; it is weaker behind, and faint at the base and infra-axillary region. Chest movement good. Exceedingly little curvature of spine." I next examined him on May 23rd of this year. He was stout, and looked in excellent health. He told me that at some athletic sports, about a fortnight previously, he had won the 100 yards race, and came in second for the quarter of a mile. He says he feels perfectly strong and well. On looking at his chest, there was little to be noticed, except that the right nipple seemed a little lower than the left, and that the chest was perhaps somewhat flattened under the clavicle. Under the nipples the right side measured about one-eighth of an inch less than the left. The side moved freely, and the percussion note was good all over. The breathing was normal, except at the base behind, and over the axillary and infra-axillary region, where it was somewhat weak. The spine was quite straight, and there was hardly a remaining trace of digital clubbing.

Remarks.—The complete and fairly rapid recovery in this case is encouraging. I suppose the comparatively early date at which the radical operation became obviously necessary, and was performed, largely contributed to the satisfactory result. It might, I think, have been performed still earlier, with the advantage of saving about a fortnight of the acute part of the illness. There has been a great variety of opinion with regard to the site of the incision and the after treatment of these cases. The recommendations of Dr. Douglas

Digitized by Google

Powell seem to me to be the most judicious that have come under my notice. The common sense view of the matter is to have the opening as low down as is consistent with safety and the comfort of the patient, and to make and keep it sufficiently free to ensure the complete emptying of the cavity. It is also necessary to take care that all air entering the cavity shall be as aseptic as possible. Of course the lowest point in the chest, whether the patient is lying or standing, would be found in the posterior wall; but an opening there involves cutting through the large muscles of the back, a procedure which might cause trouble at the time, and possibly inconvenience to the patient afterwards. I should recommend the incision to be made in the infra-axillary region as low down as is found to be safe, and as far back as is possible without exposing the larger muscles. It should be remembered how often the last traces of pleuritic effusion are found in this situation. In the present case I had intended to make the incision further back, but for some reason—I forget what—which presented itself at the time of the operation, I made it in the position described. No injections were used. They did not seem to be necessary, and it is well to avoid the *nimia diligentia*. The blocking of the aspirator gave annoyance on two occasions. This I found to be largely due to the small bore of the ends of the piece of glass tubing inserted in the indiarubber pipe. These openings on examination were seen to be less than the diameter of the cannula of the trocar I used, Potain's largest.

Jersey.

ON THE RADICAL CURE OF HYDROCELE.

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S,

ASSISTANT SURGEON TO THE MANCHESTER ROYAL INFIRMARY, AND SURGEON TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN.

THE radical cure of hydrocele at the present day is usually carried out in one of the following ways—viz., by injection, by antiseptic incision, or by excision of the tunica vaginalis.

The last of these three methods—viz., that by excision of the parietal portion of the tunica vaginalis, first introduced by von Bergmann, and described by Bramann[1]—is a plan of treatment which, so far as I am aware, has not hitherto been much adopted in this country. The operation is a simple one, and in four cases in which I have adopted it has been attended by the most satisfactory results. Bull of New York,[2] who has employed the same method in three cases, regards it as "the only truly radical operation," and speaks very highly of it. It may be performed in the following manner, which, except in a few minor details, is identical with that of von Bergmann. The cavity of the tunica vaginalis is laid freely open by a vertical incision between two and three inches in length, made over the most prominent part of the swelling; the fluid will at once escape, and, as it does so, it is useful to secure the margins of the opening in the tunica vaginalis on each side with a pair of catch forceps, otherwise there may be a little trouble in distinguishing them after the evacuation of the fluid, and the walls of the sac have collapsed and fallen together. The tunica vaginalis is then dissected out on either side up to the point where it is reflected upon the epididymis, testis, and cord, by putting it on the stretch and separating it from its connexions with the surrounding parts by means of the finger, assisted by a scalpel or pair of scissors. It is astonishing how little hæmorrhage accompanies the proceeding if the finger is chiefly used. In my last case not a single vessel had to be secured. The whole of the tunica vaginalis is then removed, with the exception of the portion covering the epididymis, testis, and cord, by cutting through it close to those structures with scissors. All bleeding points having been secured, a drainage tube is brought out through the upper part of the wound and a counter opening made at the most dependent point of the scrotum. The interior of the wound, which will have contracted very considerably, is dusted over with iodoform, closed with a few sutures, and dressed with iodoform gauze and wood-wool pad, care being taken that the scrotum is afterwards kept in an elevated position. Healing rapidly takes place, the slight swelling which follows the operation soon subsides, and the patient will usually be able to leave his bed and get about in the course of a week or ten days, as shown by the cases mentioned below. Though applicable to all cases of hydrocele, this method is especially valuable in those of long standing, where the tunica vaginalis has become much thickened and of dense consistence. As compared with the other plans of radical cure, the excision method has this advantage—viz., that it is almost practically impossible for a recurrence of the hydrocele to take place.

In the method by injection with iodine or carbolic acid (the latter fluid being now generally used), a recurrence takes place in a certain proportion of cases. Of three cases, which I have recently treated in this way, the hydrocele returned in one (see Case 3). It may be alleged against the excision method, as compared with the injection treatment, that it is more severe, and necessitates confinement to bed; but even in cases of injection the inflammatory symptoms are often so marked that the patient is unable to get about for several days. In the three cases which I injected with carbolic acid, the patients remained in hospital respectively for nine, twelve, and fourteen days after the injection before the swelling and other symptoms had sufficiently subsided to enable them to resume their ordinary occupation.

The excision method is, I think, much superior to Volkmann's plan of simply incising freely the cavity of the tunica vaginalis. The process of repair in the former is much more certain, for, if an attempt is made to obtain direct union of the opposed serous surfaces after incision, there is always a possibility of non-obliteration of a portion of the cavity of the tunica vaginalis and a liability to recurrence of the hydrocele. If, on the other hand, as commonly happens, the cavity is obliterated by a process of granulation and suppuration, healing is quite as slow as, if not more so than, in cases where the serous membrane is removed. In a case treated by incision under my care some time ago (see Case 4) the wound had not healed at the end of four months, a troublesome sinus remaining, which had to be freely laid open and scraped before it could finally be made to close. If, after excision, uniform pressure is made upon the scrotum by the dressings, so as to maintain the opposed surfaces of the deep parts of the wound in contact with one another, healing will rapidly take place, often almost without any suppuration, just as is frequently seen after removal of the testis. In the course of a few months it will be found that the scar of the operation has almost disappeared; the scrotal tissues move freely over the surface of the testis, and it requires a careful examination to detect that any operation has been performed upon the part.

Of the following cases three were treated by injection, two by incision, and four by excision of the tunica vaginalis: in each instance except one the hydrocele was of the common variety.

CASE 1. *Injection with carbolic acid; cure.*—Aged forty-four years; tapped once previously.—Jan. 13th, 1887: All fluid drawn off and one drachm of equal parts of glycerine and carbolic acid injected and left in the cavity of the tunica vaginalis; scrotum tender and swollen for about a week. On the twelfth day the swelling of the scrotum had subsided, but the testis was slightly enlarged and tender on pressure. Left for the convalescent hospital at Cheadle.

CASE 2. *Injection with carbolic acid; cure.*—Aged forty-seven years. Tapped three times previously.—Feb. 2nd, 1887: Injected as in previous case, followed by considerable effusion into tunica vaginalis. As this did not become absorbed, the swelling was tapped on the tenth day, and four ounces of turbid, port-wine-coloured fluid drawn off. No further effusion took place, and the patient left the hospital four days later.

CASE 3. *Injection with carbolic acid; recurrence.*—Aged forty years. Tapped seven times previously.—Feb. 6th, 1887: Injected as in preceding cases, followed by very slight effusion. Left hospital on the ninth day, swelling having quite subsided. A month later the patient returned with a recurrence of the hydrocele, which was treated by excision of the tunica vaginalis. (See Case 7.)

CASE 4. *Antiseptic incision; sinus for four months: cure.*—Aged thirty-seven years. Tapped once previously. On Aug. 26th, 1885, a free opening under the carbolic spray was made into the cavity of the tunica vaginalis, the edges of which were stitched to the skin, the wound being plugged lightly with iodoform gauze. The cavity contracted, but did not close, a deep sinus remaining, from which there was an abundant discharge of pus. On Dec. 17th the sinus was laid

[2] New York Medical Journal, March 13th, 1886.

Digitized by Google

open and scraped, and in the course of a few weeks it gradually healed.

CASE 5. *Antiseptic incision; cure.*—Aged nine years. Hydrocele of the cord. Tapped several times previously, and injected once with iodine. On Aug. 24th, 1882, antiseptic incision. On the thirteenth day the patient left the hospital, the wound having almost healed.

CASE 6. *Excision of tunica vaginalis; cure.*—Aged forty-seven years. Tapped four times previously. On June 30th, 1886, the parietal portion of the tunica vaginalis was removed in the way described. On the tenth day the wound was almost healed, and the patient left for the convalescent hospital at Cheadle.

CASE 7. *Excision of tunica vaginalis; cure.*—Aged forty years. Tapped seven times previously, and injected once with carbolic acid (see Case 3). On April 5th, 1887, operation; fifth day, tube removed; ninth day, wound healed; fourteenth day, left hospital for Cheadle.

CASE 8. *Excision of tunica vaginalis; cure.*—Aged fifty-three years. Tapped three times previously. On May 23rd, 1887, operation; second day, tube removed; fifteenth day, wound healed; eighteenth day, left hospital for Cheadle.

CASE 9. *Excision of tunica vaginalis; cure.*—Aged thirty-eight years. Tapped three times previously. On July 5th, 1887, operation; sixth day, tube removed; ninth day, wound healed; fifteenth day, left the hospital.

Manchester.

DR. R. KOCH'S BACTERIOLOGICAL WATER TEST.

BY G. BISCHOF, F.C.S., F.I.C.

No. III.[1]

EXTENSION OF TIME OF CULTURE.

ONE of the sources of error in Dr. Koch's method of water testing by gelatine-peptone is due to the interference, mainly, of the liquefying colonies with the culture of other colonies present. The former do not only, as a rule, more or less monopolise the area of the nutritive medium, thus preventing the free development of other colonies, but they are the principal obstacle necessitating the limitation of cultures to mostly three days, which leaves us in ignorance of what would have taken place thereafter. For these reasons it appeared to me that the usefulness of bacteriological water testing would be increased if means could be found to extend the time of culture by limiting the extension of objectionable colonies. A primary condition of success in that direction is that the samples of water and the gelatine should be mixed uniformly with the greatest possible care. The encroachment by objectionable colonies may be prevented through their destruction by heat, or by the application of antiseptics. Heat—say the introduction into the colonies of a platinum wire made red hot by electricity—might answer, but there would be too great a danger of the liquid spurting out and infecting the surrounding parts.

Experiments were on this account made with a variety of liquids, commencing with a cold saturated solution of mercuric chloride, which was introduced by means of a fine capillary tube in connexion with a small vessel containing a supply of the antiseptic reagent. Notwithstanding the employment of a magnifying glass in the examination of the plates, the difficulty then arose that after a time it was almost impossible to find out whether a colony was new or had already been treated. The solution of mercuric chloride was therefore mixed with a like volume of cold concentrated cupric sulphate, the colonies treated being thus stained and readily recognised. Several glass plates with nutritive gelatine and some samples of water having been placed in the usual way each into a damp chamber, the liquid mixture could be introduced to any part of the plates by tilting the upper dish at the place nearest to some colony. When several colonies close to each other have to be treated, the dish is supported, whilst introducing the liquid, by a glass rod properly shaped for the purpose, in order to reduce the tilting of the cover and consequent change of air within to a minimum. If the atmosphere of the laboratory is somewhat impure, it is advisable to avoid the tilting entirely, and to introduce instead the sterilising medium through a small hole bored in the upper dish near its top, closing the opening at other times by a stopper. In view of the observation made by me some time ago,[2] that culture in darkness mostly results in a reduction of the number of colonies, it may be stated that in all experiments bearing upon the extension of time of culture the samples were freely exposed to light, so as to have the most favourable conditions for the development of colonies. In four cultures of a sample of water the following numbers of liquefying colonies were observed on each plate treated with the mixed liquid:—

	Plates.				
	No. 1.	No. 2.	No. 3.	No. 4.	Average.
After 2 days	3	1	2	4	2·50
,, 3 days	0	1	3	1	1·25
,, 4 days	9	13	18	13	13·25
,, 5 days	15	7	14	14	12·50
Total	27	22	37	32	29·50

This experiment shows at once that if culture, as hitherto usual, had been interrupted after three days, a small portion only of the liquefying, and, it may be added, of all microphytes present, would have developed colonies, and that it is a mistake to suppose that the colonies capable of growing in gelatine-peptone are obtained by three days' culture. On the sixth day the experiment was interrupted, as the blue tinge almost throughout the gelatine showed that the cupric sulphate, as probably also the mercuric chloride, had spread to such an extent that there was great danger of the free development of colonies being prevented by these substances.

Only one more liquid experimented with may be mentioned—viz., a strong solution of methyl blue in absolute alcohol. Contrary to expectation, this gave a very unsatisfactory result, liquefaction being to all appearance even increased by the treatment. The explanation of this probably is that the very small quantity of the liquid, which can be added without overflow, was so diluted by the surrounding liquid that it ceased to act as an antiseptic, serving, on the contrary, as food.

After this and other similar experience a number of solid media were tried. They were in each case finely pulverised, but without being reduced to dust. Several, as coke and animal charcoal of various origin, failed to attain the object, or even accelerated liquefaction; and only two, crystallised potassic permanganate and spongy iron, were found to answer. The former offers the obvious advantage of being readily soluble. Very little of it is required to completely sterilise a liquefying colony of moderate size, and, supposing a sufficiency of the material, it is not necessary to be very particular to spread it all over the liquefied spot. After a short time it will be dissolved and disseminate throughout the colony, which henceforth ceases to increase. The permanganate does not spread at all beyond the colony, and I frequently noticed the formation of different new colonies bordering on a sterilised one. This also refers to spongy iron, which, however, mostly forms a ring slightly tinged by some ferric compound around the colony. It is difficult to understand the action of that material, as the alkalinity of the liquefied gelatine almost excludes any slight solubility of ferrous compounds such as in ordinary water. As very little only of the sterilising medium can be applied, spongy iron was selected which had been reduced by water gas, this being the purest and richest in metallic iron. Either of the solid media is introduced by means of a kind of pipette. A small bulb is blown at one end of a glass tube about the size of a quill, and a small perforation made in the side of the bulb. To the other end of the glass tube a short piece of tubing about two or three times wider is fused, and a glass stopper ground into the open end. The perfectly dry material being filled in, the pipette is closed by the stopper, then, in the case of permanganate, held vertically, the bulb at the top, so that the material recedes into the enlarged portion. The fine tube is passed in the usual way through the flame of a burner, after which the pipette is inverted so that the material fills the fine tube and bulb and is quickly introduced between the dishes. The opening in the bulb being turned downwards over a colony, the granules are spread on to it in any quantity desired, if necessary by gently tapping

[1] No. II. appeared in THE LANCET, April 9th, 1887.

[2] Journ. Soc. Chem. Ind., March, 1886.

Digitized by Google

against the dish. Spongy iron is not affected by any reasonable degree of heat, and the bulb and tube may in its case be sterilised whilst filled with the material, which should be introduced into the centre of the colony so as to form a small cone reaching slightly beyond the colony. If the colonies are not large, the cone remains dry, and one treatment is sufficient, at least for nine days, which is the maximum of time hitherto experimented on, but on the least sign of failure the application must be repeated.

In the first experiment in which permanganate was made use of as steriliser, culture was successfully extended to nine days, when 1230 total and 28 liquefying colonies were found per cubic centimetre, the corresponding plate, on which spongy iron was used, giving 880 total and 36 liquefying colonies. In regulating the quantity of water for an experiment, too many colonies on a plate should be avoided. I have had from 20 to 25 liquefying colonies, but that is about the maximum which can be conveniently treated. Penicillium and other similar colonies sometimes give almost as much trouble as liquefying colonies, but they may be sterilised preferably by permanganate, which in their case must be spread carefully over the entire colony. On the whole, permanganate seems preferable on account of its ready solubility, but, as far as my experience goes, spongy iron may be used should there be a reason to render permanganate undesirable. With a moderate number of colonies to be sterilised on a plate, one inspection, and, if necessary, treatment every twenty-four hours is sufficient, the first inspection being generally required after a sample has been cultured for forty-eight hours. Blank experiments were made, which proved that these manipulations do not with due care introduce any serious risk of infection of the gelatine; also that the several materials experimented with are not themselves productive of colonies when placed on the sterile nutritive medium. It is obvious that by the extension of culture the objection that many organisms require more than three days to form colonies, and thus escape notice, is, to some extent at least, removed.

Various opinions have been expressed as to how the merely numerical result of cultures should be interpreted. It has been asserted that the numbers of colonies found allow of a direct conclusion as to the quality of samples of water; so that, for instance, a sample in which 100 colonies per cubic centimetre have been found might be considered very good. Others maintain that a comparative construction only is permissible, inasmuch as the colonies in a sample of water are compared with those in the same sample after it has received a certain treatment—say, by filtration through sand; and that the improvement or deterioration thus effected is in a certain ratio to the number of colonies in both. I have on various occasions expressed doubt as to both these views, as some of the conclusions to which they lead are at variance with established bacteriological facts.[1] At any rate, it seems clear that what we must aim at is a distinction between harmless and hurtful microphytes in water—in fact, rather a qualitative than a quantitative test; and the standard of quality of water should be the absence or presence of pathogenic organisms. Extension of culture having demonstrated that after three days a small proportion only of the microphytes present is revealed, it seems impossible ever to decide after three days' culture that no hurtful microphytes are present in a sample. In the experiments hitherto made, culture after nine days mostly shows a very marked increase of colonies up to fifteen times, as compared with culture for three days. Even after nine days colonies continue to make their appearance, and there is no doubt that the number of organisms capable of growing in gelatine-peptone, which are obtained after nine days, might still be increased. Moreover, the longer culture is continued, the more developed are the colonies, and the more they exhibit characteristic distinctions. Interesting colonies may be protected against the invasion of others by being surrounded, say, by permanganate, and they may thus frequently be cultured on the original plate without the necessity of making pure cultures on another plate. This probably can be utilised, not only in testing water, but in pathological research generally. The utility of the extension of culture will be illustrated by reference to a practical case—that is, to an experiment made on a London water before and after filtration through sand.

On the 16th of last July a number of samples were taken both from the river Thames at Hampton and the supply of the Grand Junction Company from their standpipe at the Marble Arch, which gave the following results per cubic centimetre:—

A. *Tested at once after collection.*

I. After 3 days' culture:

Thames	2465 tot. col. ...	218 liq. col.	} Total reduc.	
Grand Junc. ...	47 ,, ...	0 ,,	} 98 per cent.	

II. After 9 days' culture:

Thames	8523 tot. col. ...	769 liq. col.	} Total reduc.	
Grand Junc. ...	202 ,, ...	33 ,,	} 97·6 per cent.	

B. *Tested after 10 days' storage.*

I. After 3 days' culture:

Thames	5908 tot. col. ...	56 liq. col.	} Total reduc.	
Grand Junc. ...	2701 ,, ...	19 ,,	} 54·3 per cent.	

II. After 9 days' culture:

Thames	45486 tot. col. ...	406 liq. col.	} Total reduc.	
Grand Junc. ...	39754 ,, ...	123 ,,	} 12·6 per cent.	

The figures show that after three days' culture and ten of storage the total colonies in the sample of Thames water were increased by 140 per cent. against 5647 per cent. in the Grand Junction Company's water. The liquefying colonies in Thames water decreased under these conditions by 74 per cent., whilst those in the Grand Junction Company's water increased by 1900 per cent. The total colonies in the latter water had thus increased about 40 times more than those in Thames water. After nine days' culture and ten of storage the increase of total colonies in Thames water was 434 per cent., in Grand Junction water 19,500 per cent. The liquefying colonies in Thames water had then decreased by 47 per cent., those in the Grand Junction sample increased 273 per cent. The total colonies in the Grand Junction water had therefore in this case increased 45 times more than those in Thames water. We shall presently have to attempt an explanation of these singular differences.

The reduction shown by the filtration of Thames water under the several conditions is: In the sample tested at once after being collected, the reduction was after three days' culture 98 per cent., and after nine days' culture 97·6 per cent., the reduction of the liquefying colonies being 100 and 95·7 per cent. respectively. After storage of the samples for ten days, the reduction of total colonies was diminished after three days' culture to 54·3 per cent., and after nine days' culture to 12·6 per cent., the reduction of the liquefying colonies being 66 and 69 per cent. respectively. The flasks used for storing the samples were provided with glass and asbestos stoppers, and not opened until the water was mixed with gelatine-peptone.

Remarkable is the difference in the effect of extended culture on the sample mixed with the nutritive medium at once after collection, and the other mixed after ten days' storage. In the case of the former there was no practical difference in the reduction after three and nine days, whilst after the storage the reduction of total colonies after nine days' culture is shown to be almost 80 per cent. less than after three days. This seems to show that, given the conditions under which life can be freely developed—that is, when the organisms are surrounded by their natural element, water,—the filtered sample deteriorates so much more than the unfiltered, that, upon the showing of the gelatine test, any gain, apparent or real, by the filtration, is in a comparatively short time apt to disappear almost entirely. This would be not unlike the patching up of cracks and fissures in a building with plaster and paint; it looks all right for a time, but soon matters are as bad as ever. There is in this no condemnation of sand filtration, which unquestionably improves river water very materially, but a condemnation of the sensational percentage reduction hitherto shown by the gelatine test.

But is it reasonable to expose samples of water to the conditions which led to the reduction in the filtered sample of only 12·6 per cent. of total colonies? There can be no doubt on one point—viz., if the test is made to yield by extended culture a much larger portion of the organisms actually present in water than by culture for a shorter time, the larger figure obtained is the more reliable, because it must approach more closely the true condition of things. More hesitation will be felt regarding storage for some days before the water and gelatine-peptone are mixed. It certainly may be argued that samples without storage represent the condition in which water is delivered by the company—that is, at their standpipe, and not in the consumer's dwelling. Keep your cistern as clean as practicable, and you probably will never find the 98 per cent. reduction. Thus I tested lately the water from the cistern

[1] Proc. Inst. Civ. Eng., vol. lxxxv., Part 3. THE LANCET, April 9th, 1887.

Digitized by Google

in my laboratory, which is very fairly clean, and through which an unusually large quantity of water passes mostly day and night. Allowing a few days for a corresponding sample of water from Hampton to reach the cistern the result was an indicated total reduction of 36 per cent. It therefore seems justifiable, as long as water is supplied by the intervention of cisterns in which storage takes place, to compare samples of unfiltered and filtered water after a reasonable storage, thus imitating the conditions under which the latter is consumed. Even then the conditions of our experiment are too favourable, because in cisterns water is exposed to aerial and other contamination, which is excluded in the sample flasks. We need not maintain that 12·6 per cent. is the correct figure, but there is no reason to give any greater claim to 98 per cent. The figures hitherto generally given might pass unnoticed, had not hints been thrown out at various times that they are to be regarded as the standard by which water companies should arrange their filters. This may lead to serious expense to them without benefit to consumers, and real beneficial progress may thus be prevented. Even were a fallacy detected in these conclusions, it is quite out of the question to place reliance on numerical results of bacteriological testing, unless the time of culture for each sample be stated.

Before concluding, I wish to guard against the inference that I accepted any one of the figures in the table to be a true exponent of the reduction effected in Thames water by the filtration through sand. It is well known that a not inconsiderable proportion of the metropolitan supply is derived from other sources besides the rivers; and had the sample of unfiltered water which was tested been a true average sample of the company's supply, the reduction would in all probability, *cæteris paribus*, have appeared less favourable. False security is a condition which before all things should be guarded against as much as possible in sanitary matters.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SYMPTOMS OF IRRITANT POISONING IN A FAMILY, DUE TO DISEASED BREAD.

BY J. CHALMERS ROBERTSON, M.B.

ON Thursday, July 9th, 1887, I was called to the house of a Mr. T——. On arrival, I found a family consisting of Mr. T——, aged forty; five children, ages varying from eight to eighteen, and a niece aged eighteen, all suffering from symptoms of irritant poisoning. Their illness had commenced almost simultaneously in the early evening of Tuesday, July 7th, with violent sickness, followed by profuse diarrhœa. They were seen twice by their usual medical attendant, who was on the point of starting for his holiday, and who requested me to take up the case.

I found Mr. T—— complaining of great pain about the epigastrium, and he seemed unable to retain anything; he had had considerable diarrhœa, but this had now ceased. The eldest son, aged eighteen, had had slight pain and diarrhœa, but scarcely noticeable. The third son had great diarrhœa; the fourth the same, but with considerable sickness. The elder daughter had sickness only; the younger was somewhat sick, but the pain and diarrhœa in this latter case were very severe, and were only with difficulty subdued. The niece had diarrhœa only. The mother (Mrs. T——), the second son, and an infant in arms escaped entirely.

It seemed clear that here was a family poisoned, and the question was, what was the cause? I at once inquired as to whether any tinned food had been eaten, but there had been none. I then made inquiry as to exactly what had been eaten during the previous Monday and Tuesday, but there was nothing which seemed to account for the symptoms. On further examination, however, as to what was eaten for breakfast on Tuesday (the morning of the day when the illness began), my attention was directed to a loaf of bread which Mr. T—— said he thought at the time "had a funny taste." The eldest son had said he did not like that bread, and ate only a small piece. The second son had none whatever, neither had Mrs. T——, nor, of course, the infant. All these facts were elicited only on careful cross-examination, as the family had not had the slightest suspicion of the loaf in question being the cause of their troubles. There was now something of which to lay hold. Every member of the family who had partaken of that loaf in ordinary quantity had been rendered ill; one member who had merely eaten a small piece felt uncomfortable; those who did not eat any remained well. Fortunately a piece of the loaf remained, the small top part of a cottage loaf. I was struck by the amount of mould upon it, although it was only five days old, and had been kept in a bread-pan in a perfectly dry cupboard, the weather at the time being, moreover, very hot. My friend, Mr. George Brownen, F.C.S., very kindly undertook the examination of this piece of bread, and in his report he said: "I can find no mineral irritant, or poison as arsenic, antimony, or zinc, and the proportion of alumina will not (by its excess) indicate alum. The sample of bread is, however, acidulous and mouldy, and this fermentation and fungoid infection has penetrated deeply, but irregularly, the substance of the loaf, and its microscopic characters are circles of green mould (mucor); capsular filaments of aspergillus (A. primigenius), feathery patches of penicillia, abundance of spores, but no insect organisms or maggots."

Parkes, in his Manual of Practical Hygiene, sixth edition, article Bread, says that "flour may be grown and fermenting, or with fungi forming. The fermenting flour produces dyspepsia and diarrhœa; the heat and moisture of the stomach, no doubt, excite at once very rapid fermentation; the glutin, already metamorphosing, acts very energetically on the starch and CO_2 is rapidly developed; hence uncomfortable feelings, flatulence, imperfect digestion, and diarrhœa." Further on, speaking of flour, originally good, but altering either from age or from not having been well dried, Parkes says: "The bread is often acid and sometimes highly so" (it was in the case under consideration). "This may produce diarrhœa, though such bread has sometimes been used for a long time without this effect; usually persons will not eat much of it. If the bread be too moist, fungi form."

Now, whether the flour was originally bad, or whether it underwent some alteration afterwards, I am unable to say, but there seems no reasonable doubt that the disease in the loaf was the cause of the illness with which I had to deal. It is quite possible that we have in undetected diseased bread an important factor in the causation of diarrhœa, and one which we would not readily suspect, and I shall be glad if abler pens than mine will take up a matter so closely related to the welfare of the community.

Wandsworth Common, S.W.

DISLOCATION BACKWARDS OF THE CARPUS AND HAND.

BY CHARLES R. WALKER, M.D.

THE following description of a case of this rare form of displacement, which occurred a few weeks ago, seems worthy of record.

Alfred C——, aged sixteen years, a grocer's apprentice, while pulling towards him with his right hand a heavy cask suddenly slipped backwards, his elbow (right) coming in contact with another cask behind him. A fellow-workman, who came to his assistance, finding the arm powerless and distorted, brought him immediately to me. The great amount of deformity was very striking. The hand was bent a little backwards, but was not abducted, and the fingers were flexed. Anteriorly, and a little below the wrist joint, was a large prominence continuous with the bones of the forearm. This consisted of the lower ends of the radius and ulna, which could be very distinctly felt. The styloid processes, conspicuously projecting, were entire, and preserved exactly their relative position. Posteriorly and a little above the wrist was another prominence which was formed by the carpal bones, the upper row exhibiting a well-marked arch under the tense skin. Crepitus was absent, as also any other sign of fracture. Reduction was easily effected, the bone surfaces gliding into apposition with a distinct jerk. He could now, though with some pain, move his wrist in all directions, and when the arm was extremely pronated he was able to supinate it. His general health seemed to be good, and there did not appear

Digitized by Google

to be any abnormal laxity of the joints generally. The limb was kept on a splint and evaporating lotions applied, and in a fortnight's time he was able to do light work, the wrist being still somewhat weak.

Remarks.—The mechanism of dislocation seems to have been as follows:—When the boy stumbled, his grasp of the moving cask tightened, and in endeavouring to recover himself the whole weight of his body was exerted on his right arm, so putting the ligaments of the wrist joint on the stretch. Almost immediately the movement of the arm backwards was arrested by the elbow sharply striking the other cask behind. The hand being fixed and bent backwards, the radius and ulna were thus easily jerked out of place. It was remarkable how easily the different bony parts involved could be recognised almost as if one were examining the bare skeleton. Moreover, the dislocation was quite uncomplicated, for the wrist was frequently and carefully examined by myself and others, but no thickening of bone or other sign of fracture in any part could at any time be detected. The peculiar and unusual deformity, the straightness of the hand, the relative position of the styloid processes, which were entire, the arch of the carpal bones, the absence of crepitus, and the ability to supinate fully after complete pronation, were sufficient aids to diagnosis from other injuries at the wrist joint.

Leytonstone.

COCAINE EXTERNALLY AND INTERNALLY.

By G. WALTER STEVES, M.D., &c.

THE value of cocaine as a local anæsthetic is now well established, and few who have carefully tested its use, either by the simple application of a solution to the skin or mucous membrane or by hypodermic injection, will be sceptical as to its efficacy. During the past two years I have used it pretty largely in general practice, and the interest attaching to the extent and variety of its applicability, both in medicine and surgery, induces me to add this note.

Externally I have found cocaine useful in neuralgias, two obstinate cases of sciatica yielding under its application; in operating on cysts and small tumours, such as ordinary sebaceous and Meibomian cysts; a fibro-cellular tumour, about two inches in diameter, was removed from the gluteal region of an old lady without the slightest pain; in pruritus ani; in stitching two cases of ruptured perineum, where the laceration was considerable; in opening abscesses in various parts; in coccydynia; in two cases of chronic articular rheumatism, where the excessive nocturnal pain resisted ordinary treatment. As an ointment I am finding its application of great assistance in the treatment of an obstinate case of vaginismus.

Internally I believe the drug to have special efficacy in certain cases of gastralgia. In two instances, one of which was accompanied by intense gastric irritability (all food and liquid being immediately vomited), the exhibition of the drug was followed by almost immediate relief. Other treatment by morphia, belladonna, &c., had been previously tried, with no beneficial results. One of the above cases was that of a hysterical young lady under my care about a year ago, who, in addition to excessive gastric pain and epigastric tenderness, suffered from a general condition of hyperæsthesia. A notice of this patient is particularly interesting, as she had been under my observation for ten days with no improvement whatever, but after the cocaine had been administered for twenty-four hours the pain was subdued, and remained so. She has not had an attack since, although previously to this similar seizures had been periodical, especially on the approach of menstruation.

The above heterogeneous collection at least illustrates some of the uses to which cocaine may be applied by the general practitioner, and possibly may suggest others. In a recent issue of THE LANCET (August 6th) there is mentioned the case of a young woman lately under Dr. Frey of Berne, in which a general condition of hyperæsthesia was associated with intense irritability of stomach and constant vomiting, where cocaine promptly relieved all alarming symptoms. We may fairly hope that as such cases of severe functional and "sympathetic" stomach derangement are so benefited, some of the distressing symptoms which so frequently accompany internal organic disease may also be alleviated by its use; so far, however, I have seen no mention of its exhibition in the latter class of cases. Its antiseptic influence might also be in its favour. Internally I have prescribed the hydrochlorate (dissolved in water) in quarter-grain doses every four hours, or oftener when the gastric pain was excessive. For external application the solutions have varied from 4 to 10 per cent. in strength.

Liverpool.

TWO MIDWIFERY CASES.

By J. H. BATTYE, M.D.

DURING the week ending August 20th I met with two remarkable cases in midwifery which I desire to place on record, as both are to me unique. One has a bearing on Dr. Oliver's "Notes on Sterility," which recently appeared in THE LANCET, and the other is remarkable for its prolonged first stage.

On August 18th, 1887, after twenty-four years and five months of married life with her present and only husband, at the age of *forty-five* I delivered a tradesman's wife of her first-born child, a male, at full term, the labour being perfectly natural and lasting twenty-eight hours from the first pains till the expulsion of the placenta. The patient is rather stout and has enjoyed very good health, and she did not suffer during gestation. There was not the usual morning sickness or any constitutional disturbance to show pregnancy; and when I first saw her on May 23rd she came to me fearing an unnatural growth, and I did not discover that she was pregnant, as in consequence of the thickness of the abdominal walls I could not feel the uterus properly; but when I next saw her, on July 13th, a great deal of the adipose tissue had disappeared, and I had no difficulty in making out the uterus and feeling the movements of the child. Before labour came on I must admit I felt somewhat anxious about her on account of her age, and because it was to me a unique case; however, my anxiety proved quite needless, as she is able to suckle her child, which is strong and vigorous, and both up to the present time have progressed as well as anyone could wish.

As a contrast to the above case with regard to duration of labour in primiparæ, another case, occurring the same week and completed the same day, gave me a record of the longest first stage of labour I have yet met with. This occurred in a coachman's wife, aged thirty, to whom I was called at 11 P.M. on Tuesday, Aug. 16th, pains having commenced at 10 A.M. On examination the os uteri would admit only the tip of the finger, so I gave her a dose of opium (tincture of opium, 15 min.) to enable her to get some sleep, and left her. In spite of the dose of opium, she had little sleep because of the pains; and on calling at 9 A.M. on Aug. 17th and examining, although the pains were good, I found the os very little dilated compared with the previous evening, not the size of a threepenny piece. At 4.30 P.M., being in the neighbourhood, I called again and found the os dilated to the size of a sixpence, not rigid, but soft, and the pains good, every ten minutes. At 11 P.M. I was called away to the case previously related, which occurred some five miles distant from this; and on my return on Thursday afternoon at 5.20 P.M., I found the os only the size of a shilling, although up till noon on the 18th (Thursday) the pains had continued every ten minutes. After noon till an hour before my return they had not been so frequent, but they occurred then at intervals of every five minutes while I was present, and yet there appeared no rigidity of the os. Having been in labour so long, I determined upon fetching Barnes's dilating bags, but before doing so I pushed up the head a little, letting down some liquor amnii, and now for the first time I felt the bulging of the membranes. On my return with Barnes's bags at 6 P.M. I found the os dilated beyond the largest size, and at 7.30 P.M. I ruptured the membranes, as the os was completely dilated. I had, however, to complete delivery by forceps at 9 P.M. in consequence of the exhaustion of the patient.

My explanation of this prolonged first stage of labour is this:—The patient had had a remarkably sick gestation, having vomited during labour till 9 A.M. on the 18th; that by the act of vomiting the child, which presented in the first cranial position, had been driven down so low in the pelvis that the liquor amnii could not get past the head until I pushed it back at 5.20 P.M. on the 18th, when for the first time I could make sure that the membranes were entire. According to the times I have given, it will be seen that the duration of the first stage was fifty-seven hours and a half. The patient has since made uninterrupted progress towards recovery.

CASE OF FATAL POISONING BY NITRIC ACID.

By WILLIAM MILLIGAN, L.R.C.P.ED., M.R.C.S.

As fatal poisoning by nitric acid is not very common, it is well, perhaps, to place on record such cases as occur.

On Sunday morning, March 26th, at 10 A.M., I was called to see a married woman, aged thirty. I found her in a condition of mental derangement, which appears to have come on very rapidly, as the night before she was assisting in her husband's shop as cashier, and although her manner seemed a little strange and unusual, no particular attention was directed to it. I took her to her room, fastened the windows, removed razors, &c., and gave strict injunctions to the husband that she was not to be left without an attendant. At 6 P.M., seeing that she was sleeping quietly, her sister left her for a few minutes, when she got out of bed, ran down a passage into a back bedroom, and then swallowed some nitric acid from a bottle, and regained her bed before her friends, who heard the noise, could reach her. I found her completely collapsed, body and extremities cold, pulse frequent, irregular, and very small. Frothy mucus oozed from the lips, and occasionally there was violent retching, but very little was evacuated. The lips and gums were chalky white, and on the chin there was a yellow stain; the tongue was covered with pale yellowish coating. The condition of collapse lasted for four hours, during which we were assiduous in applying hot bottles, &c., and ether was injected subcutaneously several times. I then gave an enema of hot spirit and water with two eggs, and in half an hour there was return to consciousness, and the patient made signs expressive of intense pain in the chest and abdomen. Hypodermic injections of morphia gave great relief. Another small nutrient enema was given about 5 A.M., and at nine the general condition was much improved. At 12 o'clock, eighteen hours after taking the poison, the patient suddenly expired. Unfortunately the coroner considered the cause of death so evident that he would not order a post-mortem examination. On inquiry from the chemist, I find he sold half an ounce of nitric acid to a lodger in the house for the purpose of removing corns. This quantity appears to be the smallest fatally poisonous dose in an adult I can find recorded.

South Tottenham.

SUCCESSFUL TREATMENT OF PRURITUS VULVÆ.

By FRANCIS TAYLOR SIMSON, L.R.C.P. LOND., &c.

MRS. X——, an elderly lady, wife of a wealthy merchant, consulted me some time back complaining of great irritation of the vulva and perineum. She was suffering from diabetes, but although under treatment the specific gravity of her urine decreased from 1049 to 1026, yet the pruritus increased in severity. In spite of all that could be suggested by myself and many of the best London consultants, life became almost unbearable. Directly she became warm in bed the irritation would commence. She would scratch herself "almost to pieces," and would frequently leave her bed half-a-dozen times during the night to sit in a bath of cold water. She tried alkaline baths, hydrocyanic acid, black wash, chloroform liniment, &c., without avail. On July 28th she came up from the country to see me, although she felt it might be in vain. I then gave her the following ointment:—Cocain., 15 gr.; aquæ dest., q.s.; lanolin., ½ oz.; to be used every night, and lotio hydrargyri nigra to be applied in the morning after bathing. Since she used this ointment the irritation gradually decreased, until it entirely left her, and long and healthy sleep returning has made life again worth the living.

Lavender-hill, S.W.

THE BOARDING-OUT OF PAUPER CHILDREN.—The Elham (Folkestone) Board of Guardians, on the 2nd inst., had under their consideration the question of the boarding-out of pauper children. The matter had been under consideration for some time past, the object of the guardians being to bring up children under such a system as should free them from the vice and contamination of life in a workhouse. It was decided to expend £2500 in the erection of three cottage homes in the village of Cherston, a few miles from the workhouse, on the principle of Dr. Barnardo's homes.

LONDON HOSPITAL.

AN UNUSUAL CASE OF SCIRRHUS OF THE BREAST; REMARKS.

(Under the care of Mr. FREDERICK TREVES.)

THE form of growth taken by the carcinoma in the case here recorded is, as Mr. Treves remarks, very unusual. The ordinary variety of scirrhus is so well known that the deviation from the typical case is seen on perusal of the account of this one, whilst the remarks appended bring the special points more clearly forward.

A woman aged thirty-seven was admitted in November, 1886, with a remarkable form of scirrhus of the breast. She was emaciated and cachectic-looking, and profoundly anæmic. The mammæ were very small. The whole of the pectoral region of the chest was studded with a multitude of small rounded nodules, that stood out like shot under the skin. The centre of the right mamma was occupied by a very hard mass, about the size of a hen's egg, composed of a series of dense round nodules loosely held together. Each separate globe was about the size of a marble, and the nodular character of the tumour was visible through the skin. The integument of the breast was of normal colour, and was adherent to the growth; the nipple was retracted, and the main part of the tumour was fixed to the pectoralis muscle. For a considerable distance round the mamma the subcutaneous tissue was occupied by widely disseminated nodules. The majority of these lay between the breast and the axilla; some extended as high up as the clavicle, others reached the middle line, while some were found scattered over the upper part of the abdomen. All these nodules were hard, round, and free; they slipped about like foreign bodies under the skin, and the integument over them was of normal aspect. The nodules varied in size from a small shot to a bean. The largest were near the heart, and the further the distance from the nipple the smaller the little bodies became. They amounted in number to over a hundred, and some thirty of these were the size of large peas. A peculiar nodular cord ran from the mamma into the axilla, where it was lost. The nodules themselves were roughly grouped along lines that radiated from the nipple. Large veins ran between the breast and the clavicle. There was a slight enlargement of the axillary glands, and also of those in the supra-clavicular region. The left breast was occupied by a precisely similar growth to that on the right side. It was smaller, but its nodular character was even more pronounced. It was free from the skin and the pectoral muscle. Around it were some sixty nodules of like character to those already described. They had not extended so far as those of the right side; none had reached the clavicle or the median line, and neither the armpit nor the abdomen. No enlarged glands could be felt in either the axilla or the supra-clavicular region. The affected regions were entirely free from pain and tenderness. The patient could only remember a slight occasional twinge in the right breast.

There was no history of cancer or tumour in any member of the patient's family, and she had had no injury to the breast. She had had ten children, all of whom are living. She had suckled each child except the last for a period not less than thirteen months. She had always had easy confinements, and had never had any trouble with the breast during lactation. The patient first noticed a small round nodule on her right breast ten months ago. The mass was close to the nipple, and was discovered by accident. She was at the time two months advanced in pregnancy with her last child, and was enjoying excellent health. The first nodule appeared in the left breast eight months ago. Fresh nodes appeared around the original ones, and, partly fusing with them, produced the principal tumours. Fresh crops of nodules, extending from the nipple area, had been appearing ever since. She was confined at full term; the labour was easy and the child is sound and vigorous. No change

Digitized by Google

occurred in the right breast after the confinement, but the left breast became swollen and tender; a little milk escaped, but disappeared in three days. She made no attempt to suckle the child. The disease has not spread more rapidly since the lying-in. For the last seven months the patient has failed in health. She has become wasted and weak. Six months ago a cough commenced, and this has persisted ever since. On admission, the patient was exceedingly feeble, and was much troubled with the cough. Her temperature was normal. On being informed that any operation was out of the question, the patient left the hospital after a few days' rest.

Remarks by Mr. TREVES.—The case is peculiar in many respects, and is, in my personal experience, unique. It is, in the first place, unusual for a scirrhus to appear during pregnancy, and still more unusual for it to involve both breasts under those circumstances. The growth appears to show in an exaggerated way the mode in which a scirrhus extends. It is well known that the extreme margin of the morbid growth shows under the microscope a disposition to form nodular masses and cords. All rapidly growing tissues that invade the lymphatics and the lymph spaces show the same tendency. An advance guard of nodules precedes the spread of lymphadenoma, and the spreading of lymphatic growths in the lung in tuberculosis is attended with the formation of nodular masses. In that form of cancer known as *cancer en cuirasse*, the skin around the mamma and far away on the chest becomes hard with the induration of cancer. The part becomes hide-bound, and the skin leathery. But I have not seen an example of this variety where a nodular disposition of the growth has been evident. It is not infrequent to find a noded cord leading from the breast to the axilla in a somewhat early stage of scirrhus of the ordinary form. I have met with an instance where the whole of the skin in the mammary region became infiltrated with cancer, apparently as a result of the very long continued poulticing of a scirrhous breast. The infiltration in this case was integumentary, and although it was not uniform, it hardly assumed a distinctly nodular character.

GENERAL HOSPITAL, BIRMINGHAM.

ANEURYSM OF THE SUPERFICIAL FEMORAL ARTERY IN HUNTER'S CANAL, PRECEDED BY ANEURYSM OF THE COMMON FEMORAL OF THE OPPOSITE LIMB, BOTH TREATED BY LIGATURE; REMARKS.

(Under the care of Mr. BARTLEET.)

FOR the following account we are indebted to Mr. Stephen Townesend, assistant house-surgeon.

J. C——, single, aged thirty-two, a tin-plate worker was admitted on May 10th, 1887, for a pulsating swelling on the anterior and inner aspect of the left thigh in the position of the upper part of Hunter's canal. For some weeks previously he had been subject to pricking pains in the region of the terminal branches of the long saphenous nerve, at the inner side of the foot and ankle, and to aching pains in the calf of the leg. He had noticed the pulsating swelling about ten days before coming to the hospital.

On admission, a swelling of the size and shape of a hen's egg was found at the point above named. It had distensile pulsation. The pulsation was controlled by pressure on the femoral artery.

The patient had never suffered from syphilis, had always been temperate, and had very rarely touched spirits. He had not been exposed to any great physical labour or any severe strain. He had an attack of acute rheumatism at fifteen, and again at twenty-one. In June, 1886, he had the external iliac artery tied by Mr. Bartleet for an aneurysm of the common femoral on the right side. Remembering the success of this operation, Mr. Bartleet determined to treat this second aneurysm (of 1887) by the ligature at once, without giving any other method a trial. Accordingly, on June 17th, he ligatured the superficial femoral about three inches below Poupart's ligament, making the incision, after his usual custom, from above downwards and outwards obliquely to the line of the artery. The vessel was tied with a single ligature of strong catgut. A small drainage tube was introduced. The operation was performed under the spray. The wound was completely healed by the third week after the operation, without the occurrence of any untoward symptom, general or local. The tumour at this period was firm, non-pulsating, and considerably reduced in size.

Remarks.—There are two or three points of interest in this case. First of all, the occurrence of aneurysm at all in an otherwise perfectly healthy young adult without any predisposing constitutional condition or local traumatic cause. Secondly, the appearance of another tumour soon after the first, and seated in the comparatively rare situation of Hunter's canal. The etiology of both aneurysms is obscure. The parents of the patient are both living and healthy. He distinctly denies ever having suffered from any venereal affection, nor does he present any signs of constitutional syphilis. His statement that he has been of abstemious habits is fully supported by his appearance. His occupation does not involve unusual physical labour, nor has he been exposed by accident to any severe strain. Many pathologists regard syphilis as by far the most common cause of aneurysm in the adult, but the occurrence of such a case as the above suggests that, as hæmophilia owes its origin to constitutional tendencies, so there may be a condition which may be termed an "aneurysmal diathesis," and, further, as syphilis is not altogether infrequent in the adult, that, in some cases at least, aneurysm and syphilis may be, not dependent, but merely synchronous conditions.

GLASGOW ROYAL INFIRMARY.

HERNIOTOMY; GANGRENE OF INTESTINE; RESECTION OF BOWEL; ENTERORRAPHY; RECOVERY.

(Under the care of Dr. FLEMING.)

WE are indebted for the notes of the following case to Mr. G. G. Ferguson.

J. C——, aged forty-eight, fish hawker, was admitted on April 27th, 1887, with large strangulated hernia. He stated that he had had hernia for twelve years, which, in spite of the intermittent use of various forms of truss, frequently came down. He always succeeded in returning it, although often with great difficulty and after many hours, during which he had severe pain and vomiting, until November 24th last (five months' ago), when Dr. Knox operated for strangulation and stitched the pillars of the ring together. He did not wear any truss, and the bowel remained up until April 22nd.

On admission, herniotomy was at once performed by Dr. Fleming, and, as the bowel was found gangrenous, it was laid open and slightly stitched to the external wound. The man did very well after the operation, the temperature never rising above 99°. A month afterwards it was noted that he was distinctly emaciating and was in low spirits, although naturally a very cheery man; he was also suffering extremely from the irritation of the fæces continually pouring out of the artificial anus, this irritation even preventing him from sleeping. In consultation it was decided to attempt resection and stitching of the bowel. The operation being fixed for Wednesday, June 1st, on the preceding Sunday he was put upon the most solid and dry diet possible; next morning he had a dose of castor oil, and as soon as it had acted freely he was confined to milk diet, and a grain of solid opium given by the mouth every three hours.

Operation.—Under chloroform, a thick ligature was first tied round the projecting end of the bowel, the ends being left long. By this means any further discharge of fæcal matter was prevented, and a distinct advantage gained in the subsequent manipulation of the bowel. An incision was made through the skin round the projecting end of the bowel and about a quarter of an inch from it, and was prolonged upwards. By putting the bowel on the stretch by means of the ligature already applied, it was easily dissected free and a portion pulled down with the mesentery. By following this the lower end of the bowel was found, and Bishop's clamp applied, one limb to each end of the bowel, leaving about an inch inside the clamps. About half an inch of this was cut off with scissors, and the incisions carried in a converging direction until they met about two inches up in the mesentery. There was thus removed a nearly equivalent triangle of mesentery, each side of which measured about three inches, along with about half an inch of bowel attached to the angles of the lower side. The freshly cut edges were then brought together by the approximation of the limbs of the clamp. The muscular and serous coats being distinctly retracted, it was easy to bring the mucous coat into accurate apposition by a large number of fine interrupted sutures of carbolised silk, the knots being in the lumen of the bowel. The last stitch or two had of course to be tied outside, but

Digitized by Google

the knots were easily pushed inside with the eye end of the needle. The peritoneal and muscular coats were then brought together by a series of Lembert's sutures, also of carbolised silk, very closely introduced. The edges of the mesenteric wound were stitched in a similar way by numerous Lembert's sutures, first on one surface and then on the other. The clamps having been removed, the places where the bowel had been compressed by it were carefully watched, until in a few seconds they ceased to be distinguishable. The bowels became immediately distended with gas, and some pressure had to be used to return it to the abdomen, during which it was proved that the joint was air-tight. The pillars were brought together, and the wound dressed with alembroth gauze.

The patient was kept under opium for five days, and fed entirely on peptonised milk. On June 8th his bowels were freely moved by an enema, and after a few days and one or two more enemata acted regularly and spontaneously. The temperature never rose above 100·4°, and this was due to intercurrent facial abscess from carious teeth. On July 16th he was dismissed well, having been kept in the hospital more than a week. A truss was ordered him to support the abdominal wall, which had been weakened by the incisions of the various operations.

ANTRIM COUNTY INFIRMARY, LISBURN.

CASE OF CEREBRAL ABSCESS FOLLOWING WOUND OF THE SCALP; TREPHINING; DEATH; REMARKS.

(Under the care of Mr. ST. GEORGE.)

N. B——, aged eighteen, a farm servant, was admitted about 11.30 P.M. on June 9th, 1887, suffering from a severe contused wound of the scalp, extending for about three inches over the right frontal eminence. The history of the injury was that while playing with some other lads at a game of throwing stones he was accidentally struck on the temple. He was stunned, but not made completely insensible. After the accident he walked into Lisburn, a distance of three miles.

On admission it was found that the patient had lost a good deal of blood, but otherwise he did not complain. The upper part of the wound was filled with a large firm clot. The wound was brought together lightly with three catgut carbolised sutures, and dressed with iodoform, without disturbing the clot.

June 10th.—Ordered a pill consisting of five grains each of blue pill and extract of rhubarb, with a seidlitz powder the following morning.

16th.—The patient complained of headache, and vomited for the first time. He had up to this gone on very well. Ordered five grains of calomel and saline draught every three hours, with ice to the scalp.

18th.—The vomiting had ceased, but the temperature had gone up to 100°. Ordered five minims of tincture of aconite with each saline draught every three hours, and to be purged again with the pills as on June 10th.

19th.—The pills and seidlitz powder not having acted, he was ordered a draught of white mixture.

20th.—Temperature 102° and the mental faculties stupid, but he is sensible and answers questions when roused. No vomiting. Ordered six grains of quinine every six hours. To continue the saline mixture and aconite.

26th.—Seems a good deal better. Temperature fallen to normal. The quinine and aconite were omitted, and he was ordered twenty minims of solution of perchloride of iron three times a day with infusion of cinchona. On examining the wound with a probe, rough bone was found at the upper angle; rest of wound healthy.

29th.—Very stupid. Lies chiefly on the right side. Conscious, but will not speak unless roused. Very thirsty. Temperature 100°. To omit iron solution, and repeat saline mixture and pills.

July 2nd.—No improvement. Complains still of headache, but lies quietly on the right side. Conscious if spoken to. Pulse 40; respiration 15; temperature 99°. To repeat the pill and omit the saline mixture. Ordered five grains of iodide of potassium, with half an ounce of infusion of cinchona, every four hours.

5th.—No improvement. Pulse 34; respiration 15; temperature 97°. Ordered half an ounce of whisky every four hours. Pupils slightly dilated; respond feebly to light. Conscious when roused. Complains of his head.

This state went on until the morning of July 8th, when he began to show signs of paralysis of the left leg and arm, and in the afternoon of the left side of his face. The pupils were dilated, and he would not speak. Mr. St. George therefore, as a last resource, trephined over the upper angle of the wound, where the periosteum was stripped off from the bone. On removing the disc of bone the dura mater bulged forwards and was incised freely. A little pus and a good deal of venous blood resulted. A drainage tube was introduced, and the whole lightly dressed with carbolised gauze. The patient was removed to bed about 10 P.M. He rallied well from the chloroform, moved his left leg and arm, put out his tongue when desired, and also swallowed whisky and milk. When spoken to he said he felt better. However, he slowly sank, and died on the following morning at 6 o'clock.

Mr. St. George made an examination of the body in the afternoon of July 9th, about ten hours after death. The head only was examined. The periosteum was very easily stripped from the bones in the neighbourhood of the wound, and there was a slight congestion of the vessels of the right parietal bone just posterior to where the trephined portion of bone had been removed. On removing the skull-cap the vessels of the dura mater were found to be greatly congested, and the dura mater itself was slightly adherent at the site of injury. There was no fracture on the internal surface of the parietal bone, and a little posterior to the trephined portion there was an abraded portion, and round this the dura mater was attached. At the point where the portion of bone had been removed was found the opening of an abscess, extending under the dura mater and into the brain substance. The abscess was as large as a hen's egg, and also opened upon the skull at the abraded portion.

Remarks by Mr. ST. GEORGE.—The great difficulties in the diagnosis of intra-cranial abscesses were in this case heightened by the slow progress of the symptoms, paralysis not appearing until the very last day, when the abscess had reached such a size as to be hopeless. Still the satisfactory results, the improvement in the patient's state by the removal of the pressure, such as the disappearance of the paralysis, the recovery of consciousness, &c., would lead me in future to trephine early, and make free drainage, if possible, of the abscess, as the best and only chance of saving what otherwise is a hopeless case.

Reviews and Notices of Books.

Pulmonary Consumption, its Etiology, Pathology, and Treatment. By C. J. B. WILLIAMS, M.D., LL.D., F.R.S., and CHARLES THEODORE WILLIAMS, M.A., M.D. Second Edition. Enlarged and rewritten by Dr. C. THEODORE WILLIAMS. London: Longmans, Green, and Co. 1887.

THIS, although stated to be a second edition, is to all intents and purposes a new work. No better evidence of the extent to which the bacillary doctrine has revolutionised our conception of phthisis could have been afforded than the contrast presented by the theories contained in the original work, published in 1871, and this. Seldom in the history of medicine has a greater change been seen in the current conceptions of a disease. Then the influence of humoral pathology had not died out, in spite of the cell doctrines which had gained so much acceptance; for, if we do not err, the theory advanced by the authors was in favour of a dyscrasia, a blood condition, and the formation of tubercle from blood products. But apart from their views, the influence of German pathology had largely overridden the original conceptions of Laennec, and phthisis was subdivided into varieties, mainly referable to inflammatory changes, to which tubercle was superimposed as a secondary phenomenon or accident, the result of infection through caseous material. The notion of infectiveness was initiated, then, long before a determined search was made for a special virus, and when this was discovered the pendulum swung back almost to the standpoint of Laennec—viz., that no phthisis could occur without tubercle, or, *mutatis mutandis*, without the bacillus. Dr. C. T. Williams has from the first recognised the bearings of the new discovery, and is as thorough in

Digitized by Google

his adoption of it as M. Sée. He has rewritten his work from this new standpoint, for in almost every page the influence of the bacillary doctrine makes itself felt. Nor is his acceptance of the doctrine at all hampered by doubts as to the origin of the bacillus or its mode of entrance into the body, for although he is forced to admit that predisposing causes play a great part, it is plain that he does not consider they are always necessary. It is, moreover, most interesting to observe how this new interpretation of the pathogeny of consumption fits in with the facts long known from clinical observation, and we may be grateful to Dr. Williams for having taken so decided a step towards proving the harmony which exists between old-established facts and new theories.

As to the matter of the book, it is on the whole well arranged and concisely stated. There are deficiencies—as, for instance, in the chapters on Morbid Anatomy, which are not so full as they might be in the detail which has accumulated in past years, and which the Brompton Hospital has done so much to furnish. But we observe with pleasure that Dr. Ewart's instructive study of the formation of cavities in phthisis receives full attention, and his doctrine of secondary infection of the opposite lung is freely adopted. Considerable space is allotted to the bacillus tuberculosis, and the history of the investigations that led up to its discovery is retold, whilst its clinical importance is is duly appraised. It will, we think, be seen that this is not so high as might be thought, but some instructive cases are given where diagnosis was aided by the detection of the bacillus in the sputum. In the chapter on Etiology the question of inheritance is discussed from the records of 1000 cases treated in private practice, which showed 48·4 per cent. with a family history of consumption, and only 12 per cent. of direct hereditary transmission. Hardly sufficient stress, perhaps, is laid upon the environment of the patients that show inherited taint, and, although not explicitly stated, it would seem that Dr. Williams thinks that a direct transmission of the virus is possible. Amongst possible predisposing causes, the influence of damp, of certain trades, of alcoholism, and of syphilis is directly mentioned; but less attention is given to the evil influence of sedentary town life and unhealthy surroundings, which have so large a share in producing the tendency to the disease or in laying the subject open to the bacillary invasion. The following summary of conclusions upon the question of infection will bear quoting (p. 88):—

"1. The evidence of large institutions for the treatment of consumption, as the Brompton Hospital, directly negatives any idea of consumption being a distinctly infective disease, like a zymotic fever.

"2. Phthisis is not, in the ordinary sense of the word, an infectious disease—the opportunities for contagion being most numerous, while the examples of its action are exceedingly rare; nevertheless, its communicability is possible under extremely favourable circumstances.

"3. In the rare instances of contagion through inhalation, the conditions appear to have been—(1) close intimacy with the patient, such as sleeping in the same bed or room; (2) activity of the tubercular process, either in the way of tuberculosis or of excavation; (3) neglect of proper ventilation of the room.

"4. In addition to the above, a husband may, though he rarely does so, infect his wife by coition; and this risk is considerably increased in the event of pregnancy.

"5. Infection through the milk of a tubercular cow, in cases where the udder is affected, is possible.

"6. By the adoption of proper hygienic measures, such as more ventilation and separation of consumptive from healthy people at night, and by proper care being exercised about the selection of cows for the milk supply, all danger of infection can easily be obviated."

These conclusions are perhaps such as are warranted by present knowledge, but we venture to think that time will require their modification in more than one particular.

Before describing in detail the several varieties of consumption, the authors contribute chapters on the clinical symptoms of consumption in general, including one chapter—all too brief—by the veteran stethoscopist, Dr. C. J. B. Williams, on the physical signs; and on certain special phenomena, as hæmoptysis, temperature, diarrhœa, albuminuria, and pneumothorax. The chapter on Temperature in Phthisis is one of the best studies of clinical thermometry that we possess; and it contains a series of observations which have been for the first time made in a sufficiently large number of cases and on a systematic plan with praiseworthy care and elaboration. The average curves resulting from these observations, which were carried on for several years at the Brompton Hospital, are most instructive; and of particular interest is the fact that, in spite of pyrexia, there is in a very considerable proportion of cases a gain in weight attributable to feeding, which more than counterbalances the wasting influence of pyrexia. The thermometric curve is described as being the balance between the two factors of increased metabolism and of constitutional depression or lowered vitality; so that, according as one or other prevails, there are supernormal or subnormal temperatures. Another study nearly as elaborate is that on the albuminuria of phthisis, the pathology of which is mainly to be found in lardaceous disease evolved by the phthisical process. In the greater proportion of cases the kidneys were lardaceous, in others fatty. Diarrhœa is attributed (1) to dyspepsia (as in the first stage), (2) to tubercular ulceration, and (3) to lardaceous disease; and abundant clinical illustration is given of these three types. In the chapter on Pneumothorax the most interesting fact is the record of four cases of recovery, with little or no effusion, which were observed many years ago, and are well worthy of preserving in view of the recent interest in the subject. But, of course, in the majority of cases the supervention of pneumothorax (like the rupture of a pulmonary aneurysm into a cavity) is one of the final events, and is of the worst omen. It is only in those rare cases of "apparently healthy" individuals that one may venture to regard pneumothorax with equanimity. A description of the several clinical varieties of phthisis (in which we regret to see the retention of the term "scrofulous") occupies several chapters, but need not detain us; and an elaborate statistical analysis concludes the clinical part of the work with the Duration of Pulmonary Consumption.

But, after all, the study of the disease, pursued as it is here with so much care and elaboration, and illustrated by numerous cases from an unusually rich field of clinical experience, leads us up to one subject—that which is most important, and yet most difficult—namely, treatment. Some readers may turn first to these last chapters, to learn what is to be said by the latest authorities upon this question. Here, again, we find the predominant influence of the bacillary doctrine, all measures being directed either to destroy the parasite or to enable the organism to withstand its ravages. The measures directed to maintaining nutrition, the regulation of diet, the promotion of exercise, the residence in a suitable climate, the prescription of cod-liver oil and of digestive tonics,—these, and other means for improving the general health, are as much indicated on the bacillary hypothesis as on the older doctrines. It is needless to say that all these measures receive adequate notice, with many valuable hints upon dietary, clothing, and habitation. Dr. Williams's experience of the employment of compressed air baths as prophylactic, but not curative, is worthy of attention. A chapter is devoted to Climatic Treatment, which, although necessarily condensed, is nevertheless full of suggestion, and we gladly welcome the extended list of conditions which contra-indicate the resort to mountain

Digitized by Google

climates, for these are often too much neglected. Dr. Williams says:—

"The cases where the mountain treatment is of greatest benefit are those of ordinary first-stage phthisis, where the physical signs do not amount to more than a few crepitations audible at one apex, with slight dulness and bronchophony, where the cough is not troublesome and the expectoration is scanty, though containing a few tubercle bacilli, and where loss of flesh and night sweats have continued for a few months." (Page 374.)

Similar appropriate reference is made to the suitability of the milder climatic resorts and to the value of sea voyages. As to medicinal treatment, naturally cod-liver oil receives the largest share of attention, and the value of stomachics is chiefly as an aid to the digestion of this fatty substance. Of antipyretics, the palm is given to the latest introduced—viz., antifebrin,—although exhaustion from the sweating it entails is a drawback. Under the head of Palliative Treatment are discussed measures for dealing with hæmoptysis, diarrhœa, pneumothorax, laryngeal ulceration, and other complications; whilst the final chapter deals with the Antiseptic or Bacillicidal Treatment (including intra-pulmonary injections and the drainage of cavities), from antiseptic inhalations to the gaseous rectal injections of Bergeon—methods which can hardly as yet be said to have advanced beyond the experimental stage.

We have thus cursorily passed through the pages of this work, and we may congratulate Dr. C. T. Williams upon its general excellence and the painstaking care with which he has brought the subject up to the level of modern ideas. It is a fair and faithful record of the outcome of personal observation and an extended acquaintance with the labours of others. The style in which it is written is sober and judicious. It may lack the vivacity that embellishes the writings of the French school, and in some parts we may miss the profundity of the German; but it nevertheless faithfully reflects the knowledge of the day, and may be profitably consulted by the medical practitioner, who has few diseases to deal with which more tax his judgment and his skill. We are, moreover, glad to meet once more, in the two chapters which he has contributed to the work, with the writing of one who more than a generation back led the van in the field of pulmonary pathology. We are reminded in the perusal of the work that, much as our conceptions of disease may alter, and valuable as may be the new facts discovered by new methods, nothing can change the import of facts accurately observed and carefully recorded, whereby our conclusions are rendered sounder and more complete, whilst our hypotheses are held in check.

On some of the Mental Affections of Childhood and Youth. Being the Lettsomian Lectures delivered before the Medical Society of London in 1887; together with other papers. By J. LANGDON DOWN, M.D. Lond., &c. London: J. and A. Churchill.

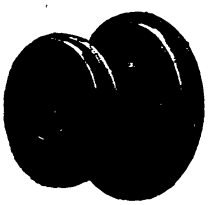
THIS valuable contribution to psychological literature is due to a request from the Medical Society of London that the lectures delivered there by Dr. Langdon Down should be republished. To these lectures are added certain "fugitive" papers, as the author calls them, printed in chronological order. The first impression created in the mind by this work, is that it takes its origin from the pen of one who writes, not because he wants to say something, but because he has something to say. When we are told that a period of nearly thirty years spent among children with various phases of mental affection might entitle the author to bring before the Medical Society material which could only be accumulated by few, we cannot do otherwise than anticipate hearing something in medicine which is at least original. And this expectation is fully realised.

Commencing with a sketch of the history of the education of the idiot, Dr. Down tells us that steps in this direction were at first isolated efforts under the guidance of M. Séguin at the Bicêtre, that in 1842 Dr. Guggenbuhl established a school at Abendberg in Switzerland, and about the same time M. Saegert at Berlin engaged in the instruction of idiotic deaf-mutes. In 1846 a school was established at Leipzig, and soon afterwards the subject was amply ventilated by Mrs. Plumbe, Dr. Andrew Reed, and Dr. Wilbur. In 1858 Earlswood Asylum first came into existence, and Dr. Langdon Down undertook the superintendence.

Now a word of criticism as to nomenclature. Dr. Down would apply the term "imbeciles" to subjects of senile changes of nutrition. He says: "I know of no defining limitation between so-called idiocy and so-called imbecility. The division, therefore, into imbeciles and idiots is thoroughly misleading. I have no great liking for the term 'idiot.' It is so frequently a name of reproach. The word 'idiot' means 'solitary.'" As far as we remember, Dr. Fletcher Beach equally condemns the word "idiot." He believes it to be an insult to call a person an idiot. In the first nomenclature of diseases of the Royal College of Physicians, published some twelve years back, a "high" idiot was to be called an imbecile, and a "low" idiot an idiot. The word "idiot" is derived from ἰδιώτης, a private person, meaning probably in ancient Greece or ancient Rome that an individual so-called ought to be kept in seclusion. Of course, the value of all the terms are very much changed since those classical distinctions were enunciated. Still, with all deference to Drs. Down and Beach—we must recognise the value of the terms "idiot" and "imbecile," as adopted in the first nomenclature of the College of Physicians, as, in the first place, bringing to the mind concisely the condition of the patient, and, as far as we can judge, being neither of them likely to offend the unfortunate persons to whom they are applied. Dr. Beach would call all idiots "imbeciles," and Dr. Down, with still more consideration, would call them all "feeble-minded"—that is, subjects of amentia,—while he would reserve the term "imbecile" for subjects of dementia, senile or otherwise.

But we turn with much pleasure to the author's original sub-divisions of idiocy. We have always conceived that the sub-divisions of Dr. Ireland, classical though they may be, are yet guilty of somewhat overlapping one another. Doubtless Dr. Down has studied Dr. Ireland's and M. Séguin's views on this subject. What, however, appears to us to be the chief merit of Dr. Down's work is that his sub-divisions, although appearing somewhat fanciful at first, are yet founded on principles of real practical importance with regard to prognosis. Briefly speaking, he makes two sub-divisions. Under the first, Ethnic, he includes Malay, North American Indian, Mongolian, and Caucasian. The last named, the Caucasian, is alone accidental—that is, produced by causes operating after birth. The other ethnic types are invariably congenital. And upon this point depends much in prognosis, at least as regards improvement. But as we proceed we find another classification, based on the etiology of the cases. And this, as the author says, is valuable from its practical bearing. This classification includes the forms congenital, accidental, and developmental. "Congenital" idiocy requires but little explanation. "Accidental" implies that some accident or some extension of disease equivalent to an accident had wrought on the cerebral centres disastrous changes, interfering with intellectual manifestations. On investigating, however, a large number of cases, Dr. Down became familiar with many instances which it was impossible to include in either of these categories. There was no history of accident or of any illness akin to accident. There was a cessation of the increasing intelligence which had marked the child's early career. Anxiety was felt on account of the deferred

Digitized by Google



speech; and this is frequently connected with second dentition. In the same category are those who, although they may have passed the first and second dentition harmlessly, break down at the time of puberty. The physical and mental phenomena in such patients are described at great length, and throw much light upon the similar cases which we all have to deal with, although displaying less marked symptoms.

Of course, in the work before us we meet with several collections of observations with which we are already familiar, but which we are grateful now to find engrossed in a permanent form for more convenient reference. Such are the causation of idiocy, the influence of alcohol in its production, of phthisis, of marriages of consanguinity, and the influence on the offspring of "over-education" in women. In this list may also be specially mentioned Dr. Down's previous papers on the condition of the mouth in idiocy, on the relation of the teeth and mouth to mental development, on the obstetrical aspects of idiocy, and various pathological communications which will bear comparison with those emanating from the researches of any sub-section of the Pathological Society. Dr. Down's book on idiocy is the most trustworthy work on this important and interesting subject.

New Inventions.

THE "SIMPLEX" MECHANICAL TELEPHONE.

THIS instrument is intended to be employed over short distances only, and is useful in warehouses, hotels, hospitals, and dwelling houses. No batteries are required for this telephone, and there is nothing in the instrument to get out of order or which requires replenishing. A single instrument acts as transmitter and receiver at each end, the two being connected by a tight steel wire which is conducted by special insulators. A great recommendation of this telephone is its moderate cost, which varies from 30*s.* to 60*s.* a set, according to circumstances. From personal experience we can testify to the simplicity and efficiency of the apparatus. The inventor and patentee is Mr. T. Harding Churton, of Park-square, Leeds.

DRAINAGE SCHEME IN THE LOWER THAMES VALLEY.

A CORRESPONDENT sends us the following account of the new system of sewage treatment which is in course of trial at Acton. There is much in the scheme which seems promising, but we are unable as yet to express a positive opinion in regard to it:—

"The Acton parish has soon followed the suit of some of the other local athorities along the Thames valley in providing for its district a system of sewage disposal, which enables it to pass into the river Thames a clarified effluent water, instead of polluting crude sewage. Acton would seem to have taken rather an enterprising step in this matter, by adopting a system of sewage purification which has not hitherto been in operation at any public sewage works. The system is that of the International Water and Sewage Purification Company, which differs in many salient points from the generally prevailing 'lime process' of sewage clarification. In this case no lime, indeed, is used. The principal substance in this new system is magnetic ferrous carbon—prepared from a murky material hitherto considered useless—rich in ferrous alum and carbonised iron. In the process of precipitation this magnetic ferrous carbon is used in combination with what are termed 'compound sewage salts,' consisting of proportions of sulphate of alumina, sulphate of magnesia, and sulphate of calcium. The company, it seems, do not claim to have made a discovery of any new substance with startling properties. The operation and effects of the process are based upon well-known chemical principles, and it is in the mode of preparing and applying this substance to the purposes of water and sewage purification that the company think they have found something which goes a long way to solve the problem of treating sewage effectively and economically. It is found that by virtue of the soluble iron and alumina salts in this magnetic ferrous carbon it acts as a rapid precipitant, and, being carbonaceous and porous, that it also acts as a disinfectant and deodoriser. The complete process of clarification does not end in precipitation. In order to render the effluent water faultlessly pure, it is passed through a bed of magnetic spongy carbon and sand. At Acton it was noticed that the effluent water as it came direct from the precipitation tanks bore a reddish tinge, but chemical testing proved that this discolouration was due to the presence of iron, which would have a purifying effect than otherwise upon the river water. But the effluent water, after being passed through the bed of magnetic spongy carbon, appeared quite bright and clear. A telling demonstration of the purity of the filtered effluent was the fact that a number of gold-fish were swimming about gaily in a large globe filled with the filtered effluent. The sight proved a most interesting one to the many sanitary engineers present at the opening of the works on Thursday week last. A recent analysis showed that as much as 96 per cent. of putrescible organic matter in solution was removed, as also all suspended matter. It would seem that here is solved the question how to secure a pure effluent without the use of lime, and without the necessity of acquiring large areas of land for irrigation, or also without the pecuniary and sanitary risks attending a sewage farm. The filter-bed at Acton, where the scheme is to provide for the requirements of a population of 20,000, occupies an area of less than seventy feet square, magnetic spongy carbon being so efficacious that it can operate in a considerably less space than most of the filtering materials made from clay deposits or earthy substances carbonised. It is well known that the stratified structure of these latter substances interferes with their filtering powers, except in the direction of the laminæ, and are therefore liable to silt up and become impervious to moisture. Another feature of the new process is the character of the resultant sludge. The liquid sludge passes from the precipitation tanks into a rotatory agitator, where more of the company's chemicals are added, for the purpose of producing practically a second precipitation, to further ensure the impossibility of putrefactive changes taking place in the solid sludge after being pressed. The company contend that by their treatment of the sludge the manurial qualities in it are fixed by the further addition of the magnetic ferrous carbon, and that if the same quantity of lime had been added, as is the case in the lime process, the manurial properties in the shape of ammonia would be driven off, and the phosphoric acid rendered insoluble and of no use to plant life. A ready demand is therefore expected for the sludge, which is to be sold as manure in powder."

ROYAL COLLEGE OF SURGEONS.—We extract the following from the *Builder* of the 20th ult.:—"Messrs. Higgs and Hill of South Lambeth, contractors, are carrying out the designs of Mr. S. Salter of Woburn-place, architect, for the addition of another floor, in two stages, to the front portion of the Royal College of Surgeons in Lincoln's-inn-fields. As it now stands, that building is mainly the work of Sir Charles Barry, who (1835–7) extended the front to 108 feet, and designed the massive Ionic portico. The original structure had been erected by Dance on the removal thither of the College from their Hall in Old Bailey—site of the now Sessions House and Criminal Courts—upon their incorporation in 1800. John Hunter's anatomical collection was opened to view here in 1813. In 1836 the Museum was enlarged, and again some years later, when the Fellows acquired possession of the ground in Portugal-street, at the rear, which had been the site of the Lincoln's-inn-fields Theatre or Duke's playhouse. About the middle of the eighteenth century the theatre was converted into a soldiers' barrack, and then into an auction-room. It was finally demolished in August, 1848, having latterly served for Spode and Copeland's china warehouse."

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 10, 1887.

OUR columns show that the Ninth International Medical Congress has been already duly opened, and doubtless by the time our impression of to-day reaches its destination will have become practically a matter of history. It is no light compliment to the profession of medicine that the President of the United States should have graced the initial stages of the Congress with his presence and co-operation, and that he should have been supported and followed in this by Mr. BAYARD (Secretary of State), who delivered an eloquent address, and expressed his belief that medicine constituted the noblest school of human usefulness. It is said that a thing well begun is half completed. And this may fairly be said of the International Congress. The details to hand of the addresses in the Sections do not enable us yet to estimate the scientific value of the Congress. We must wait patiently for fuller reports of the papers. But we learn that 5000 physicians were in attendance, and, as will be seen by our report by cable, there has been great range of subjects, and great cordiality of hospitality, crowned by an evening reception at the White House by President CLEVELAND and Mrs. CLEVELAND. The United States, regarded as a government, have hitherto been rather loose in their recognition of medicine as a profession. Each State has had its own regulations for the promotion and supervision of medical education and qualification, and the best Americans would be the first to admit that for the most part these regulations are very lax and inadequate, allowing of a great deal too many medical schools, and making medical qualification far too easy. It may reasonably be hoped that the President and his distinguished colleague will carry away from this International Congress deeper impressions of the grandeur of the medical calling, and of the responsibility of States for requiring that those who follow it shall give some substantial guarantees of general and medical education such as alone can fit them for coping intelligently with disease and guiding the public in medical questions, for acting, in the happy words of Secretary BAYARD, "as guardians of the nation's health." Mr. BAYARD would seem to have indicated that, in his opinion, the best thing that States could do for medicine as a science was not to interfere with it. This is not very complimentary to the State, which really has immense power, which it ought to use, for encouraging such a beneficent and important branch of knowledge as medicine. It must have struck him that all the members of the Congress and of similar Congresses were those who bear some mark of State recognition. Even the United States do not carry out their favourite doctrine of non-interference with the practice of medicine. Their medical schools and the recognition of some qualifications for practice, wherever and however obtained, are still matters of State regulation, however vague and various this is when we compare one State with another. A little reflection on the ubiquity of disease, and of the enormous suffering which it entails, will make it apparent to such men as the President of the United States and Mr. BAYARD that the efficiency of the medical art ought to be a chief concern of governments, and that, in the medical sense of the word, above all others *salus populi suprema lex*. Public medicine is now with us a most vital part of State responsibility, but ordinary curative medicine is no more to be neglected by wise governments than a good water supply or cheap supplies of sound food. In this sense the presence of such distinguished representatives of the nation in the Ninth International Congress is most gratifying to us, and will, we doubt not, be productive of good fruit.

The interesting address of the President, Dr. DAVIS of Chicago, will be found in another column. It would be vain to deny the disadvantage to the Congress caused by the death of the lamented Dr. FLINT, who was so ardent in the promotion of international amenities, and so open to the reception of light from all quarters as to cross the Atlantic almost annually, and to go, at an advanced age, to Copenhagen to arrange for this present Congress. It is gratifying that his name still figures honourably in the records of the Congress, and that his son, Dr. AUSTIN FLINT, read an able paper, from the physiological standpoint, on Fever: its Causes, Mechanism, and Rational Treatment. We await with interest further reports, and are gratified meantime at the auspicious opening of the Congress, and the association with it of the highest representatives of American influence and Government.

ADMIRABLE CRICHTONS, equally conversant with all departments of human thought and human work, are impossible in this age, and it therefore happens that various branches of science are, from year to year, represented on the presidential chair of the British Association. Last year we had for president an eminent geologist, and this year a distinguished chemist. Sir HENRY ROSCOE brought from the laboratory of BUNSEN, the birthplace of spectroscopic analysis and of so much else which has moulded modern science, a training in research which he has put to good account in England. We owe to him not only many good and useful discoveries, but an important impetus to chemical education and a more general recognition of its value. His election to Parliament was regarded with mixed feelings by chemists, who, while feeling proud that their science had found so able a representative, could not forget the risk that the new duties might involve an abandonment of the scientific work from which so much was hoped.

When the President is a chemist, we look for an address in which Chemistry and the cognate branches of science form the chief features, and generally for a review of the recent progress of the science. Upon Sir HENRY ROSCOE a further duty naturally fell, for in the jubilee year he could hardly avoid a history of the great scientific events of the last fifty years. No one living was better fitted for the task, for in the well-known treatise which he, in conjunction with Professor SCHORLEMMER, is giving to the world, an historical sketch has been prefixed to almost every chapter. Accordingly, we find in the presidential address a narrative which leaves but little to desire. It was unfortunate for Dr. SCHUNK the president of the Chemical

Digitized by Google

Section, that his address was necessarily preceded by one which could hardly fail to throw it into the shade. Dr. SCHUNK was indeed unfortunate in a double sense, for not only did he follow ROSCOE in this, but CROOKES in the last annual meeting. His address was interesting, but it was far below the standard set by Sir H. ROSCOE, and still less could it compare with the brilliant speculation or scientific poem in which Mr. CROOKES held his hearers spell-bound last year.

The President's address opened with a graceful tribute of respect to those two great Manchester worthies, DALTON and JOULE; the former even now remembered by a few, the latter still living in the highest honour among us. Both of them may fairly be described as the founder of an empire in science, although neither broke the first ground. The empires are those of matter and of energy. Many men not less illustrious sided in their conquest and final union, and a vast area still awaits discovery and annexation; but no one now doubts the reality of the past conquests, or their supreme importance to mankind. The idea of atoms has been supplemented by that of molecules, and all scientific men hold them, not as finalities, but as temporary expressions of the ever-growing truth. The hypotheses which now prevail, and which are at present essential to research, may, and perhaps will, take a very different form ere long, but we cannot doubt that in one form or other they will stand the verification of future discovery. JOULE'S greatest achievement was the experimental determination of the mechanical equivalent of heat, and the importance of this cannot easily be over-estimated. It led to the recognition of the doctrine of conservation of energy, which is entitled to precedence even over the great law of gravitation.

In the fifty years' survey with which the presidential address is mainly concerned we are presented first with the immortal labours of LIEBIG and WÖHLER. LIEBIG clung to "vital force," although he did more than anyone else to demolish it in its old acceptation. But his labours placed organic chemistry, and with it the chemistry of agriculture and physiology, upon a new basis. He erred, of course, and his tendency to sarcasm served to intensify his errors. He scoffed at substitution, ignored for the most part organic synthesis, and was persistently wrong in his conception of fermentation changes and the origin of muscular power. But in addition to the vast mass of fact which he, with his great colleague, collected, he revolutionised ultimate organic analysis, gave to chemistry the conception of the radical, and laid down lines of chemical classification which are still valuable aids in the science. Even the term "vital force" is only wrong if it be taken as implying creation of energy during the phenomena of life. Heat, electricity, gravitation, and chemism must still be reckoned as different forms of the force which causes energy, and we cannot as yet with any certainty identify the cause of nerve-energy with any one of them. As long as the secret of life is hidden from us we must be cautious while admitting the great law of conservation how we deny the possible existence of a force as different from electricity as electricity is from heat or gravitation. DALTON'S greatest work was done before the Victorian half-century, but it stretched into it, and its influence animated the whole. Among the most interesting passages in Sir HENRY ROSCOE'S address were those in which the modern calculations of the size and velocity of motion of atoms, or, more correctly, of molecules, were discussed. As to size, we are not indeed able to see them, but it does not seem quite impossible that one day we may. A microscope can magnify 8000 times. If the image so formed were again magnified 8000 times—if, so to speak, one microscope could take up the work of another, some molecules at any rate would be visible, although even then the velocity of their movements would probably prevent one seeing them. Hydrogen molecules are said to move with an average velocity of seventy miles per minute. Not less interesting is the account of the law of periodicity in atomic weights, which was first observed by NEWLANDS, and afterwards developed by LOTHAR, MEYER, and MENDELEJEFF. At the last meeting Mr. CROOKES exhibited a diagram, suggested in part by Professor EMERSON REYNOLDS, in which the most recent extensions of this law were shown in a zig-zag line, irreverently described by the wits of the Association as the "chemical corset." Sir HENRY ROSCOE supplied another illustration, not, indeed, diagrammatic, but verbal, which was effective and suggestive, though in a different way. We must refer to the address for the details, but it consisted in placing side by side a few simple pedigrees, with the dates of birth of each individual. Taking these dates as from left to right, and following the same order in each horizontal line, the numbers follow progressively, though with variations in the intervals. Each perpendicular column then represents a family in which common traits may be expected, and there will still be a periodicity throughout the whole. One cannot help being reminded here of Dr. STERRY HUNT'S hypothesis, in which, rejecting DALTON'S theory, he seeks to account for all chemical phenomena by evolution, differentiation, and integration of species.

Space prevents us from following the presidential address through its remaining sections. Spectroscopy received a full share of attention, as did thermal chemistry—a branch of the science which is rapidly replacing by absolute numbers the tables of affinities which figure in old treatises. Nearly all other branches of physical chemistry were brought under review, and subjected in many cases to keen criticism. Organic chemistry, with its wonderful modern syntheses and discriminations of structure, vital phenomena, and pathological chemistry, were also considered.

THE terrible fire at the Exeter Theatre, with its fearful sacrifice of life, comes so quickly after the calamity at Paris when the Opera Comique was destroyed, that it would be difficult to say anything that should not seem stale or commonplace on the subject. Nor is any useful purpose to be fulfilled by mere sentimental remark. It is very regrettable that such holocausts should be offered; and all that can be urged in favour of additional precaution to avoid "accidents" of this class may be urged with peculiar fitness on the present occasion; but we must be excused for leaving to others the practice, but too common, of heaping blame upon some person, or persons, to be singled out—a builder, or licensers, or managers of this or that particular place of amusement—as responsible for what has occurred. In truth, the fault lies at the

Digitized by Google

door of the community as a whole, rather than at that of any individual or persons. Of course theatres, of all places of concourse, ought to be so constructed as to render escape in an emergency easily practicable. Meanwhile, we have no hesitation in stating that what happened at the Exeter Theatre might almost have happened round a bonfire on Salisbury Plain if a crowd had been equally panic-stricken. It is the panic, with its blind rush of scared and selfish people, that constitutes the *immediate* cause of the calamity. If only the crowd could be controlled, and its exit made quietly, no life would be lost; whereas where there is a mad struggle to escape, some must fall, and others will stumble over them. The same thing occurs in rushes on level ground and in the open air.

If we really desire to go right down to the bottom of the evil, it is necessary to look very far beneath the mere surface facts of a calamity like that which has befallen the playgoers of Exeter. What a panic-stricken crowd really needs is control by authority. Even in this last melancholy occurrence, when the manager appeared at the door of the pit, being recognised, his presence inspired confidence, and he quickly succeeded in clearing that portion of the house without either loss of life or accident. If he could have appeared at the exit from the gallery, it would have been just the same with that portion of the audience, and the one hundred and seventy lives might have been saved. Had the exit been twice as wide and easy as it was, given a panic and without control, the calamity would have been proportioned to the number of persons panic-stricken, rather than to the insufficiency of the way of escape. The lesson to be learned from this and many other facts in connexion with the present and similar calamities is that there ought to be stationed in every separate part of the auditorium one or two officials who should be recognised as especially charged with the safe custody of the audience. They should not be attendants, or police constables, or firemen, but officials wearing a distinctive uniform, and having a status above that of the persons to whom we have referred, so that they might both command respect and inspire confidence. It would be well if a distinct corps could be formed, under the control of the Home Secretary, and independent of the theatres, though the force might be supported by contributions levied on the lessees of places of amusement. To this corps the sole duty of protecting audiences should be entrusted. It would be their business to see that all doors of exit were open, and that every means of escape were practicable. They should have nothing whatever to do with extinguishing a fire, but be held directly responsible for the safety of the audience and for help in its bewilderment. A panic-stricken crowd would look to these officials for protection, and it should be made imperative to submit to their direction. Those who know most of human nature will be aware that even in the wildest excitement there is an underlying desire to be controlled, and a firm authoritative guide will seldom fail to assert his supremacy. The first condition of respect in an emergency is confidence; and the knowledge that a particular official, of suitable physique and instantly recognisable by his uniform, was present, would cause the majority to look to him instinctively for help. This mental attitude alone would render escape more easy.

What we would urge is that in each part of an auditorium of a theatre one or more of these officials should be placed, and that they should be held responsible for taking means to clear the particular part of the theatre entrusted to them with safety to the outgoing crowd. As to the cost of maintaining such a corps, suppose it amounted to a tax of five pounds, or in some cases a larger sum, per night for a theatre, that would not be an unfair impost for the management, considering how greatly it would conduce to the popularity of theatres which are now avoided by no inconsiderable number of persons, simply because they are afraid to frequent places of amusement, knowing that in any moment of danger there is sure to be a panic, and that when it occurs there will be no sort of control or protection, but everyone will be thoroughly selfish and intent only on his own personal safety. The knowledge that a special corps of life-guardians was in attendance would conduce more to confidence in general, and coolness in any critical moment, than any other means that could be devised. We commend the suggestion to those upon whom the provision of means for the public safety devolves, and by whom something must be done, or outraged public opinion will assuredly begin to revolt.

IF we may judge from the amount of attention and space that medical literature is devoting to the subject, one of the dark fields of pathology which is about to receive at least some if not a flood of light is gastric disease. We do not, and in fact cannot, expect any very great advance to be made in this obscure subject without the preliminary settlement of certain elementary considerations. Thanks largely to the laborious investigations of the German physiologists, we may now say that it looks as if in the near future some definite methods will be discovered by means of which we shall be enabled to assert whether any particular stomach which may claim the attention of the scientific physician is or is not in a healthy condition, and this information we expect to be obtained on data other than can be supplied by the patient. We are fast approaching to the acquisition of sound knowledge in respect of the duration of the digestion of various articles of food, and of the causes which tend to delay the departure and accelerate the disappearance of food in the stomach, but we are yet in want of a definite and workable method of estimating the acidity of the gastric juice, and of recognising the bodies to which this acidity is to be attributed. It is sincerely to be desired, for the sake of scientific clinical medicine, that some means may shortly be devised applicable to individual cases, and capable of being used in diagnosis. It cannot be denied that diagnosis needs further elaboration when we bear in mind the poverty of our resources in this regard. Some years ago some hope was engendered by the announcement in a rather enthusiastic way by, we believe, a considerable continental authority, that in all cases of carcinoma of the stomach the juice removed from that organ by means of a tethered sponge was devoid of hydrochloric acid, whilst the succus similarly removed from the stomachs of patients suffering from other diseases than carcinoma contained hydrochloric acid in recognisable quantity. This discovery, had it been one, would have

Digitized by Google

proved an incalculable boon to clinicians, but observations made since the announcement have shown, we believe satisfactorily, that cases of carcinoma of the stomach are not always marked by the absence of hydrochloric acid in the juice, and, on the other hand, that cases of gastric disease, which to all appearances are not carcinomatous, yet possess the negative quality of being found wanting in hydrochloric acid. BENO LEWY has studied cases in which great atrophy of the mucous membrane of the stomach was attended with suppression of the secretion of hydrochloric acid. M. GRUNDZACH has examined the contents of the stomach of several hundreds of individuals who did not present any signs of carcinoma of this organ. In five of the cases examined, the hydric chloride was invariably absent. Now, although all the five patients were dyspeptics, yet their ages (about thirty) and the absence of any other symptoms, with the very long duration of the dyspepsia, would seem sufficient to negative carcinoma. In none of them was there any interference with the mechanical functions of the stomach, for this again emptied itself in the usual space of time required by healthy organs. The integrity of the motor mechanism of the stomach in these cases seems to show that it is the aliment and not the gastric juice which sets the contractility of the walls of the stomach in action; though it is quite possible for a very acid juice to excite undue manifestations of contraction with too rapid emptying of the stomach, which may be followed by characteristic diarrhœa.

The question of the presence of dilatation of the stomach appears to be more fully studied abroad than at home; and we cannot but think that this possible factor in gastric conditions has not always received the consideration it merits. Of course we refer to the idiopathic dilatation, supposing it to exist, and not to that which is secondary to obstructive disease of the pylorus. GERMAIN SÉE believes that dilatation may be due to degeneration of the muscle of the stomach walls, to atony of the organs associated with general asthenia, and to a special muscular atony which, after having alternated with phenomena of exaggerated excitability, in neurasthenicæ, finishes by becoming predominant and persistent. In cases of simple muscular atony, which may be due to congenital feebleness, as ALBERT MATHIEU again suggests, the stomach, incapable of resistance, is passively distended under the influence of the pressure if not the weight of the aliment. The importance of dieting such an alleged case is only too apparent, and, whether the pathology be correct or not, we can bear personal testimony to the value of suppressing such articles of diet as green vegetables, salads, green fruits, and potatoes, except in the smallest quantities and especially prepared. The number of meals may be increased, whilst the amount taken each time should be very small. MATHIEU demurs to the use of adulterated wine, and thinks beer may be drunk, but only with the meals. For the relief of painful sensations M. SÉE recommends the employment of hot drinks—weak tea in the morning and light "grog" in the evening. In order to regulate the bowels in such cases, he advises the taking of a powder composed of magnesia, cream of tartar, and precipitated sulphur, mixed in equal proportions. To promote the general tone of the patient tepid and cold douches are advised, preferably of the shower-bath description, and lasting from twenty-five to thirty seconds, repeated every other day. It has been somewhat aptly said that gastrectasis is in some fashion a kind of asystole of the stomach, and that as we require digitalis for the heart, so some medicament of similar action on the stomach is needed. Nux vomica is employed, but ipecacuanha is more successful according to others, and may be administered in syrup of orange; it does not avail, however, if the muscular fibres are degenerated as well as atonied. Chloroform water and hydrochlorate of cocaine, as well as warm drinks, may be employed to relieve the gastralgia.

IF it be true that coming events cast their shadows before, it is equally true that past events leave their shadows behind. The repeal of the Contagious Diseases Acts has produced the most disastrous results in all the English and Irish districts where they had been previously enforced. As has been before noticed in these columns, the present condition of these places is exactly the reverse of that which was reported by the Select Committee of the House of Commons in 1869. It was then: "Prostitution appears to have diminished, it worst features to have softened, and its physical evils abated." At the present time it is notorious that prostitution has largely increased; its worst features—shameless solicitation in the streets, the increased number of juvenile prostitutes and of brothels—have become hardened; while its physical evils in the form of syphilis and gonorrhœa have been greatly intensified. In India it would appear that the authorities have had the experience both of the benefits of the Acts and of the disastrous results of their repeal. The consequences have been that efforts are being made to re-enact the Acts in Calcutta. The Health Society of that city and other advocates of sanitary reform are striving hard to regain what has been lost, and to defend what has still been maintained—a law relating to cantonments, locally known as Act III. of 1880, which has lately been experimentally suspended with the worst possible results. These efforts are being pursued in the midst of an agitation similar to that which has been so active and so unfortunately successful in England. The persons who are so engaged seek to prevent the re-enactment of the Acts in Calcutta, and also to ensure the repeal of the local Act just alluded to. It is greatly to be hoped that they will be unsuccessful, and that wiser counsels will prevail. In the *Journal of the Health Society of Calcutta* there has been recently published a paper giving some facts and figures which show very conclusively both the benefits of legislation and the terrible evils resulting from its withdrawal. It appears that the Surgeon-General of Bengal reported in 1884 that "no sanitary improvement could possibly be brought to more absolute demonstration than the vast decrease of the worst of the contagious diseases in Calcutta, and its practical disappearance from the garrison under the working of the Act of 1868." Statistics confirm this. Among the garrison the ratio of syphilis was 10 per cent. of its whole strength. It sank in 1869 to 9 per cent., in 1870 to 6 in 1872 to 5·7. It never again reached 5 per cent. while the Act was enforced, and was in four years less than 2 per cent. The statement previously made, that it practically disappeared, is therefore no exaggeration. In

Digitized by Google

1883 it rose at once to 10 per cent. in consequence of the Act having been suspended, and in the following year to 30 per cent. In that same year (1884) the large proportion of 58·14 per cent. of the garrison suffered from some form of venereal disease. Such has been the effects of repealing the Act in Calcutta; and it is well known to the military and naval authorities at home that the prevalence of disease among our troops and seamen is at least equally, if not more, severe. Those who are acquainted with India will know well that prostitution is there a matter of "caste," and that the daughters of prostitutes are from their birth inevitably doomed to that life. It is, therefore, not surprising to learn that the Act has met with no opposition from them, since it has proved the best friend they ever had, saving them from more disease and suffering than all that has ever been either accomplished or attempted by philanthropists. The statistics already given of disease among the troops give some indication of what must have been the condition of these women before the Act was passed, to which state they have by the suspension of this beneficent measure been permitted to return. When the Acts in England and Ireland were suspended in 1883, and repealed in 1886, much surprise was expressed by certain peers and members of Parliament that the members of the medical profession did not send in a memorial in their favour. Some went so far as to express indignation as well as surprise. On behalf of the profession, it may be said that any such proposed memorial would, after all that has been said and done by its members both individually and collectively on behalf of these Acts, have been entirely superfluous. It is well known that these Acts have the support of all the leading members and of an overwhelming majority of the whole of the medical profession. It is not for the profession but for the public to decide the question. All that concerns the former has been long since settled in favour of the Acts. If the prevention of loathsome diseases among the unfortunate prostitutes in garrison towns and naval seaports, as well as among the soldiers, sailors, and civilians, be not a sufficient reason for restoring the Acts, the time is not far off when such restriction will be demanded for a less worthy reason—the financial one. Once let it be established that these diseases are more costly than the means to cure them, and self-interest will effect what more worthy motives have failed to accomplish.

Annotations.

"Ne quid nimis."

MEDICAL EDUCATION AND INFECTIOUS DISEASES.

THE remarks of Professor Haughton of Dublin, in the recent discussions in the Medical Council, on the necessity for insisting on students seeing the infectious fevers and the treatment of them as a vital part of their education, receive a striking confirmation in a report to the Corporation of Newcastle-on-Tyne by Mr. H. E. Armstrong, medical officer of health, on the subject of a recent outbreak of typhus. This disease of late years had until very recently been rare. In many towns it has probably been entirely absent for years. Unfortunately, the disease at the present time appears to be likely to be more rife in the metropolis, several cases having, within the last few days, been received in the hospitals of the Metropolitan Asylums Board. Still, it would certainly be possible for students to go through their ordinary curriculum in many schools and not see one case of typhus. Mr. Armstrong says that at the present time no English university or medical examining body requires compulsory attendance at a hospital for infectious diseases as part of the curriculum for its degree or diploma, with the exception of the University of Durham. This is rather a strong statement; but if any contradiction of it is possible, the sooner it is made the better. If not, we commend it to the committee now charged with a consideration of the best methods of increasing the practical element in medical education. To have such statements made to corporations, and repeated in the daily papers, is not calculated to increase the public respect for medical education, or for the Medical Council. It is no answer to such an assertion to say that the infectious and eruptive fevers cannot be treated in general hospitals. It would be improper to treat them there except under the most exceptional circumstances, and with the extremest care. But they can now be studied on a large scale in hospitals set apart for such cases, and they can be largely studied in private practice under conditions of pupilage. In the face of such statements as Mr. Armstrong's, we think the Medical Council will neglect its duty if it does not make very plain representations to the examining bodies on this point. It is said that difficulty sometimes arises from the reluctance of medical students to visit wards or cases of an infectious character; but we trust this is a libel. Certainly no student is worthy to enter the medical profession who is not prepared to take all such risks as are involved either in learning or practising his profession.

METROPOLITAN DUAL CONTROL.

UNDER the above heading *The Times* publishes an article by a correspondent which discusses the anomalous position in which the Metropolitan Asylums Board are placed, by having to provide hospital accommodation for all persons suffering from infectious disease, whatever their social position may be, and he points out that this has arisen from the omission of the metropolitan sanitary authorities to exercise the powers conferred upon them by the Sanitary Act of 1866. In this matter, however, these authorities are less to blame than the Legislature, which imposed a duty upon district bodies which could only be properly performed by one acting for the whole metropolis. Serious difficulties have arisen in consequence, and residents in London have been slower to resort to institutions through which the only medium was the relieving officer, than would have been the case had the hospitals been a branch of sanitary administration. The increased facilities which now exist for the admission of cases of infectious disease have led to the much larger use of the hospitals of the managers, and no doubt tend to exaggerate at the present time the evidence that London is suffering severely from scarlet fever. The statement on Wednesday that there were 1067 scarlet fever patients in these institutions ceases to excite the same alarm when it is considered that the cases are in the proportion of 1 to 4000 of population, and that the disease is of an especially mild type; this fact deserves to be remembered, for the free publication of statistics of the epidemic is undoubtedly conveying to many minds the belief that a more serious calamity has befallen London than is really the case. That Londoners thus willingly send the sick to hospital is matter for congratulation; and the writer above referred to expresses the sentiment of all engaged in preventive medicine when he suggests that the cost should fall upon the community rather than upon those who have sought isolation. The removal of infectious persons

Digitized by Google

from houses in which they cannot remain with safety to other persons is so distinctly of advantage to the public, that it would be false economy to discourage removal by taxing the patient with the cost of his maintenance.

RECOVERY IN A SUPPOSED CASE OF MYXŒDEMA.

DR. F. W. WARFVINGE, a Swedish physician, has published an account of an interesting case occurring in a carpenter's apprentice, aged nineteen, who had previously enjoyed good health. About eight weeks before admission into hospital he began to be easily tired, and when he walked suffered from pains in the legs, and especially in the calves. At the same time he began to "see double." Besides these symptoms, it was noticed that he would repeat the same questions over and over again. His legs began to swell first, and then the swelling extended to other parts of the body. Gradually his intellectual as well as his physical powers diminished; he became apathetic and indifferent to what was going on about him, and lay half asleep most of the day. When he got up he experienced considerable difficulty in standing, and could not walk without assistance. He also had difficulty in retaining his urine, which did not present an altogether normal appearance. He was admitted into hospital on March 31st, 1886, and then presented the following symptoms: Appearance very apathetic; face rigid, wanting in expression, bloated, with the more prominent parts effaced. All the rest of the body was swollen, without there being any true œdema. On the lower extremities, where the swollen appearance was most strongly marked, the pressure of the fingers produced a slight impression, which immediately disappeared. The skin was everywhere infiltrated, thickened, of an elastic hardness, dry to the touch, of a dirty grey colour, with a slightly cyanotic tinge on the lips and cheeks. The neck was short and thick. No trace of the thyroid body could be detected on palpation. The patient suffered from general nervous depression; he was incapable of any occupation, and dull and indifferent to what was going on about him; his memory was defective, and he did not remember what had only recently occurred. He could not walk unless he was supported under the arms, and his gait was slow, heavy, awkward, and dragging. He moved his arms slowly and with difficulty, and could only exert a slight pressure with the hand. His sensations were blunted. He did not complain of any pain, slept well, had a fairly good appetite, and his bowels acted regularly. The respiratory and circulatory organs presented nothing abnormal. The blood was found to contain the normal number of red and white corpuscles. No enlargement of the spleen. No albuminuria either then or subsequently. At first the quantity of urine passed per diem was rather low, being only 900 to 1000 cc., and sometimes there was difficulty in retaining it. The temperature was normal all through. He was treated by hot baths and solution of arsenite of potassium (liquor arsenicalis), of which four drops were given three times a day. He soon began to improve, progressing slowly but uninterruptedly till he left the hospital, after having been in it thirteen weeks. His control over his muscles had not then quite returned, and his gait and other movements were still somewhat awkward and embarrassed. In other respects he appeared to be in good health, his skin had regained its normal appearance, and he had for a considerable time been able to make long journeys without fatigue. His mental condition also had become quite normal. After a course of baths during the summer he presented an appearance of perfect health, and this he has retained for a year. Though the symptoms in this case appear to indicate its identity with other cases of myxœdema, it differs from them in the rapidity of its course, and in the ultimate recovery of the patient, for the disease has hitherto been looked upon as incurable. Whether the arsenical treatment had anything to do with the favourable issue is a matter upon which Dr. Warfvinge does not wish to offer any opinion.

THE SANITARY CONDITION OF CAPETOWN.

Mr. EASTON deserves the thanks of the inhabitants of Capetown for exposing in a public lecture recently delivered the terrible and dangerous condition of the slums of that city. The municipal authorities and the police had given him, he said, every assistance in his investigations, which, indeed, would otherwise have been simply impossible. In the course of his peregrinations two rooms were pointed out to him not twelve feet square, in each of which fifteen persons, men and women huddled together, had slept for the night, in addition to which the passages had been lined with human beings right through to the back yard and into the yard itself. He had himself stepped over the sleeping bodies in the passages and rooms as he passed through a house, and could well believe that he did not on that occasion see the worst. He went on to say that at the east end of the town he saw a room about ten feet by twelve, occupied by fifteen Kaffirs, packed almost to suffocation, and in a state of indescribable filth. He remarked: "I sometimes think that if all the inhabitants were bent on suicide, and had made up their minds to bring about and die of typhoid fever, they could not do more towards compassing their desired end. It is a standing invitation to all forms of disease and death. But there is something more horrible still. In those parts of the town, where the masses of the poor, the idle, the dissolute, and the criminal congregate, there is a terrible percentage of disorderly houses of the very lowest type, spreading far and wide the most loathsome of diseases, so that one might say without exaggeration that here you have to deal with a seething mass of corruption brought about both by the vices of the people and by their filthy surroundings." He was much struck with the absence of elderly people, and on mentioning this to someone, he was told "they all die off; drink and living in such dens were more than the strongest constitutions can stand." As all these unclean specimens of humanity have votes, this may be one reason why no serious attempts are made to cleanse the Augean abominations. Each of the four sanitary districts has one inspector, but Mr. Easton suggests that three or four more ought to be appointed. Probably, however, it will require the visitation of some fearful epidemic to awaken the authorities to any real sense of their responsibilities.

A PLEA FOR SUPRAPUBIC LITHOTOMY.

DR. T. SVENSSON of Stockholm, having practised all the recognised methods of operating for stone in the bladder, has had complete success since he commenced to perform the suprapubic operation for large stones and in severe and complicated cases. He has performed this operation with various objects, and he considers it by no means dangerous in itself if it is only executed with the necessary precautions (in two sittings, with antiseptic methods, a cautious injection into the bladder, &c.). Thus he removed by suprapubic lithotomy, or spicystotomy as he terms it, a stone nearly as large as a hen's egg, from an old man, who was extremely weak, and who was suffering at the time from senile gangrene affecting the foot and the lower part of the leg. A few weeks later amputation had to be performed through the thigh; but the patient was afterwards sent to his home (which was at a considerable distance) completely cured. Dr. Svensson does not invariably perform the operation at two sittings, and he does not resort to it, of

Digitized by Google

course, in all cases of stone. Lithotrity at a single sitting, litholapaxy, as well as median lithotomy, always, he considers, present their own indications, which is not the case with the lateral operation. In the performance of suprapubic section, he agrees with Petersen that plugging the rectum, while at the same time the bladder is filled, contributes in a marked degree to facilitate the operation and to render it free from danger. Complete suture of the wound is not generally desirable, but the application of some sutures to the bladder serves to check posterior hæmorrhage, and may be requisite for this purpose. Usually before opening the bladder Dr. Svensson passes a running noose of thread through the wall of the bladder so as to include the line of incision, thus providing a remedy in case hæmorrhage should occur. His experience is that posterior hæmorrhage occurs in an eighth of the cases if sutures are not applied to the wound in the bladder. He endeavours to show that the suprapubic operation is safer than other methods, the patient recovering more rapidly than after litholapaxy, the pain also being very slight. An additional advantage is on the side of suprapubic section: it is available for other affections of the urinary passages, and without it some of these diseases would be incurable. He hopes in a subsequent paper to give an account of his experience in the Sabbatsberg Hospital.

SCARLET FEVER IN LONDON.

As many as 156 cases of scarlet fever were admitted into the hospitals of the Metropolitan Asylums Board during the week ending September 2nd, and the resources at the disposal of the managers are being seriously taxed. Stockwell Hospital, which has 322 beds, will, it may be anticipated, receive a considerable number of patients during the present week, and probably by the end of the month the whole of the accommodation which the five London hospitals can provide will be exhausted. Already there are more than 1000 patients under treatment in these institutions; no diminution in the epidemic can be hoped for until after the first week in October, but in all probability from that time it will decline. The managers still have at their disposal the hospital at Winchmore Hill and the hospital ships, and these should serve for any increase during the few weeks of epidemic prevalence that remain. It is interesting to note that, notwithstanding the large number of persons who are attacked, the deaths from scarlet fever are below the average for the same period during the last ten years. There is reason for congratulation that no single case of small-pox has been admitted during the past week into the managers' hospitals, but enteric fever and typhus are making some demands for accommodation.

PHYSIC AND PHYSIOLOGY FOR FOOLS.

ONE of the most melancholy features of present day journalism is the rapidity with which it is becoming the medium of the propagation of false physiology and falser physic. It would be ludicrous if it were not so pitiable, as showing how ignorance is rampant, that such lucubrations as have been published of late in one of the most widely circulated of our London evening papers should ever have been permitted to be inserted with all the honours of type and position. The writer, whose name and address are appended to his contributions with the affix "M.D.," is, we may observe, not to be found in the Medical Register. Indeed, a few extracts from his latest advocacy of "Apples as Food" speak for themselves, and carry with them their own condemnation of the scientific pretensions of the writer. The article is headed a "Remedy in Consumption." It opens with the information that "Consumption is nothing more than a specific deviation in the nutritive process by the withdrawal of free phosphorus," and goes on to say that the blood of the consumptive is deficient in this element and in fibrin. The reader is further informed that "fibrin is the formative or nutritive portion of the digested food advanced into the final state of preparation for organisation"; that "while retained within the channels of the circulation it builds up various structures of the nature of tendon and gristle." Also that "tubercle is caused by a deficiency of fibrin and phosphorus, for fibrin cannot be formed without phosphorus in the blood"; that "multitudes of important vital agents called *phosphoric cells* ..... which are endowed with a kind of vitality ..... convert the raw albumen of the chyle into vital fibrin." It appears, according to this authority, that "the tuberculous constitution is "deficient in these phosphoric cells," and "this is one step at least in accounting for the deficiency of fibrin"—and so on in the same strain through another column, all leading up to the precious conclusion that a diet of apples, potatoes, and tomatoes, or the administration of their infusions by inhalation (!) forms the sovereign remedy because they furnish a supply of free phosphorus. It is insulting to the intelligence of the community that such sorry stuff as this should be found in the columns of a newspaper, even in the "silly season." Carlyle's memorable dictum is not far from the truth, if this is to be the kind of instruction accepted by mankind.

MORPHIINOMANIA.

OF late years we have become painfully alive to the fact that the too rapidly increasing total of luxuries which accompany civilisation includes the use of opium for other purposes than the treatment of disease, and that this misuse of the drug is by far less exceptional than it has been. In an article in the *Nineteenth Century* for this month, Dr. Seymour Sharkey refers to the inroads which this detestable vice is making into health and happiness, especially on the Continent, but also in this country. The picture which he draws of the consequences that certainly follow this form of indulgence is by no means overdrawn. The false ease, the relapse into misery, the failure of function, mental and bodily, the moral perversion, the difficulty of reform—these are no new features in the history of the opium-taking habit. Deliverance from its baneful mastery is, happily, not impossible; but we need not say that here the great superiority of prevention over any method of cure whatever is clear beyond all need of proof. The habit of morphia or opium taking is formed, as a rule, in either of two ways: it may begin as an idler's pastime, a quasi-scientific diversion; or it may be formed almost accidentally out of the legitimate use of the drug as a medicinal agent. In a sense, it may appear hardly necessary that we should seek to impose the restraint of our advice on those with whom this practice is a mere amusement. They know the danger which lurks within their newly-found pleasure; it is a matter of common notoriety; but they are confident of their skill to avoid it. Why warn them further? To argue thus, however, is only to fold our arms in the presence of the enemy, and it is also evident that the consequences of this hurtful custom in many cases do not light only on the offender himself. We must therefore remind any who may be lingering over this temptation that they have not to do with a luxury in which moderate indulgence is either natural, healthful, or even possible, but with a substance which, taken in health, can only injure, and whose power can only be gauged by painful reflection. On behalf of that other class in whom the habit is formed by past experience of relief of pain, we would strongly deprecate the over-confidence which occasionally induces such patients to treat any symptoms of discomfort or pain by having unauthorised recourse to the

Digitized by Google

old remedy. We cannot in such cases insist too strongly on the necessity of retaining the use of a drug so seductive yet so powerful exclusively within the province of the physician. As regards the treatment of the established habit, it is even more true of opium than of alcohol that no middle course is possible between abstinence and infatuation. The vice of morphinism, if it is to be abandoned, must be at once and totally relinquished. The privation will indeed be felt, but not for long, and the freedom finally attainable is worth the effort.

SIR W. R. GROVE, F.R.S.

THE retirement of Mr. Justice Grove removes, happily without extinguishing, one of the brightest ornaments of the English Bench. Events, and especially scientific events, move so fast nowadays that it seems quite an age since Mr. Grove, as he was in 1847, received the Bakerian medal of the Royal Society for his lecture on Voltaic Ignition. And, measured by events, an age it is. But it has dealt very kindly with Sir William Grove. It has crowned his early labours with abundant success and assured to him a lasting place in the memory and affections of the world of science. The author of the now classic essay on the "Correlation of Physical Forces," and the inventor of the "gas voltaic battery," bears a name which will be remembered and revered when the recollection of his legal career is preserved only in law books. But that will not be just yet, for the impression of his urbane manners and judicial bearing will not easily pass from the recollection of his contemporaries, even of those who only saw him from the unenviable position of litigants. We cordially wish him a long enjoyment of that *otium cum dignitate* which he has so well earned and is so eminently fitted to adorn.

OPHTHALMIC PRACTICE IN RUSSIA.

DR. KUBLI has recently published a report of the last five years' work of the ophthalmic out-patient department of a St. Petersburg charitable institution. The number of cases reported on is 23,286, all being adults, as children's eye diseases are provided for in a different institution. The most common affections were, of course, those of the conjunctiva, which comprised more than 10,000 of the total number of cases; next to these came affections of the cornea and sclerotic (5000). There were 213 cases of glaucoma and 449 of diseased lens (cataract?). Amongst the rarer forms of ophthalmic disease there were noted 6 cases of tarsitis of syphilitic origin, 5 of amyloid degeneration of the conjunctiva, one of partially persistent pupillary membrane, one of cysticercus in the vitreous, and one of hysterical amblyopia. Dr. Kubli prefers yellow wax and olive oil as a basis for ointments. He has seldom been obliged to resort to total extirpation. For acute and gonorrhœal conjunctivitis he has tried corrosive sublimate in solutions of various strengths. The 1 to 10,000 solution was very badly borne; the 1 to 15,000 was too irritant; the 1 to 20,000 was borne well, but it was of doubtful efficacy, and when used for a length of time not infrequently set up erythema, œdema, and eczema of the lid. He prefers a 4 per cent. solution of boracic acid or chlorine water to corrosive sublimate, carbolic acid, or salicylic acid. A 2 per cent. solution of jequirity was tried in a number of cases of granular lids without any satisfactory result. In phlyctenular conjunctivitis, he prefers dusting with finely powdered iodoform to calomel and iodol applications. In severe ulcerating and purulent corneal affections, he has employed eserine and pilocarpine with good results. For tattooing leucomas he prefers a simple Lüer's needle, such as is used for conjunctival incisions. After applying very finely powdered indian ink to the surface with a spatula, he pricks the latter all over with the needle held obliquely, and then rubs the indian ink into the punctures with an indiarubber spatula. In atrophy of the optic nerve, subcutaneous injections of chloride of thebine (thebinum muriaticum), containing 0·001 to 0·003 gramme, were tried without any effect.

THE HOMELESS POOR.

THE vagrants who sleep in Trafalgar-square, on the benches in St. James's Park, on the Thames Embankment, and other public places, must be regarded as evidence of considerable poverty, such as was the forerunner of typhus in the days when epidemics of this disease were more frequent than they are at present. The absence of typhus from London, to which we have become accustomed, must not blind us to the fact that we have still in this great city ample material in which it can develop; and if it should be found that there is exceptional poverty, and a cold winter should supervene, sanitary authorities may have to exercise considerable vigilance to prevent an outbreak. Already there are some indications of the existence of this disease in London. Two cases have been removed during last week to the hospitals of the Metropolitan Asylums Board from Bethnal-green and from separate houses, one from Islington, four from two houses in Whitechapel, and one from another house in the same district; thus one week's record shows that six houses have been invaded. Occurring early in September, these cases cannot but be regarded as ominous, and we may look with some anxiety to the time when winter gives increased opportunities for the development of this disease. It is a matter of much importance to know the manner in which typhus has been introduced into the metropolis, and whether these cases have any relation to one another. The hope of guarding against further introduction must depend upon this being done; yet, likely enough, apart from such inquiry as we may anticipate will be made by the health officer of each district, there is no central department that will concern itself with these occurrences. The risk to London is seriously increased for want of this organisation.

EELS IN LONDON WATER MAINS.

IT will be remembered that during the course of last year numerous complaints were made by the inhabitants of West Ham as to the existence of eels, both alive and dead, in the water pipes of the East London Water Company, and that the circumstance was attributed to the giving way of a filter at Lea Bridge in 1879, subsequently to which the eels had bred and multiplied in the filtered water, and even in the mains. Public inquiry into the matter was at last instituted, and it was held by Major Scott, water examiner, and by Mr. W. H. Power, of the medical department of the Local Government Board. In a very elaborate report they entirely dispose of the preconceived notions as to the source from which the eels came, and they express their conviction that the eels obtained direct access to the interior of the Old Ford reservoir. In explaining the process by which this took place, some very interesting material as to the natural history of eels is supplied. It has somewhat recently been ascertained that full-grown eels are in the habit of descending rivers towards the sea each autumn, and that each spring myriads of minute eels ascend the rivers, coming out of brackish waters and penetrating to the furthest limits of inland streams. A gravid female eel and the male eel have, however, as yet never been seen. Then, again, it is explained that eel fry in their journey up stream have a great power for surmounting what appear to be impassable barriers by climbing ashore and passing overland. Now adult female eels and their young, whether discontented, as the report suggests, with the flavour of the polluted Lea, or for other reasons, would

Digitized by Google

find in the shelving banks by the Water Company's works the best of opportunities for favouring their whim for wandering ashore, and it would be but a little distance to the attractive and grass-clothed roof of the reservoir. Disporting themselves here, they would find no difficulty in dropping into the reservoir itself by means of apertures in manholes and ladder holes, and, once having gained admission, their migratory instinct and their lack of adequate food would doubtless lead them to start on a journey *down stream*, whence they would soon find themselves pumped into the mains. This explanation of the existence of eels in the water mains appears a much more satisfactory one than any other put forth, and it avoids the difficulty, inherent in any other hypothesis, of explaining how eels, however small, could pass through the pinhole apertures in the screens, which are so placed as to prevent the passage into the reservoir of any such objects from the river. The conclusions arrived at are well reasoned out, and the report is one which possesses a good deal of general interest.

GRANULAR OPHTHALMIA IN THE RUSSIAN ARMY.

DR. TALKO, writing in a Polish journal on granular ophthalmia (trachoma) in the Russian army, gives it as his opinion that the reason why this affection is always rife in the army is that recruits who are suffering from it are accepted, and they doubtless infect others. In the year 1885, 8350, or 67·2 per 1000, of the recruits were returned as "trachomatous." In some years the number of recruits affected has been as high as 10,000. The different arms of the service seem to be affected in very different proportions. Thus, while 83·6 per 1000 of the infantry, 59·9 per 1000 of the engineers, and 23·8 per 1000 of the artillery were affected, the disease was unknown amongst the Cossacks. This Dr. Talko accounts for by the fact that the Cossacks are not kept so much in barracks as the others, but are exercised more in the open air, besides which the disease is not met with among the young Cossacks on the Don.

GRAND CANARY AS A HEALTH RESORT.

AMONG the more important papers read at the recent meeting of the British Medical Association was one by Mr. Mordey Douglas of Sunderland on the virtues of Las Palmas, on the N.E. coast of Grand Canary, and long since described in the gazetteers as the largest, most beautiful, and most populous towns in the Canaries. Mr. Douglas enters into a minute comparison of the respective advantages of Oratava, the capital of Teneriffe, expresses a very decided opinion in favour of Las Palmas, and gives the following as the principal points of advantage: (1) a much larger amount of sunshine; (2) as regards the Atlantic, a drier air; (3) as regards the winds, a drier air; (4) as regards rainfall, a drier air, because of greater rapidity of evaporation, to say nothing as to quantity; (5) a much more invigorating climate. This element of invigoration in the air is by Mr. Douglas specially associated with the north-east trade wind, which, beginning in the calm region of the Tropic of Cancer, almost constantly fans the eastern coast of Grand Canary with its gentle, dry, invigorating breezes; whilst the island of Teneriffe, being on the outer edge of the trade wind, is, according to Mr. Scott (Elementary Meteorology, p. 423) during the winter enveloped in the south-west moist counter current. As regards the temperature, the mean of the six coldest months is 63·10°, and the daily range is 10·86°. Though slightly warmer than Madeira, it does not feel so, owing to the refreshing trade wind. Mr. Douglas considers the climate of Las Palmas specially suitable to cases of phthisis of a pneumonic origin, but would expect it to prove beneficial in cases of chronic bronchitis, kidney disease, rheumatism, or the infirmities of age. As regards the last class of diseases, the proximity of home and of high medical and surgical skill is not to be overlooked. Mr. Douglas speaks feelingly on the subject of the *Gran Canaria* as having been apparently saved by it from a dangerous phthisical condition. He went branded with the words "no hope," and came back in comparatively obvious health, and we believe he means to give still further proof of his belief in the climate by returning to it for another winter. Las Palmas is said to be easily reached from Liverpool by the excellent steamers of the British and African and the African Companies, one of which sails every Saturday. It is to be regretted that the time allotted to Mr. Douglas did not permit of his giving his clinical facts and cases in support of the strong opinion he has expressed in favour of Las Palmas as a climate for phthisical and other diseases. It is desirable that such information should be published. The unfortunate events in the Riviera last year naturally increase the embarrassment of physicians and patients in deciding on a place of winter resort. Besides, the whole subject of a suitable place and climate for the delicate and the phthisical is under special discussion just now. The old notion of shutting them up in a simply warm place is very considerably discredited, and replaced by a strong conviction that purity of atmosphere and a refreshing or invigorating element are equally essential and indispensable. Even a cold atmosphere for certain cases is beneficial, and to all the invigorating element is highly valuable. Under these circumstances, we commend to all practitioners a careful perusal of Mr. Mordey Douglas's address, by which, we think, he has made a valuable contribution to climatic therapeutics.

GLANDERS IN A WOMAN.

A WOMAN, aged twenty-seven, was admitted into St. Thomas's Hospital, under the care of Dr. Hadden, on Aug. 26th. The patient lived with her husband in a mews in New Kent-road. It seems that the woman used often to attend to the horses, and her sister declared that "she was more like a man about the stableyard than a woman." About a month before her admission a horse died from "inflammation of the lungs" in a stall adjoining the room in which the patient lived. It was stated that the horse had no discharge from the nose. About three weeks later another horse died, and the husband attributed his wife's illness to contagion from this animal. The woman began to feel ill about a fortnight before admission, but did not take to her bed until a week later. She was clearly in a dying state when seen on admission: she could not respond when questioned, was constantly muttering, and the hands and lips were tremulous. The lips were dry and covered with sordes, and the tongue was coated with dry, yellowish-brown fur. The respirations were shallow, 50 per minute; the pulse 120, and very feeble. The cutaneous affection was of a twofold nature: there were a limited number of small cutaneous abscesses, mainly on the chest, and rather a larger number of raised red lumps, varying in size from a shilling to half-a-crown, corresponding to deeply seated inflammatory centres. No enlarged glands were detected. There was no discharge from the nose, and no affection of the conjunctivæ. The temperature rose from 103·8° on the day of admission until it reached 108·4° on the evening of the next day, when she died. At the post-mortem examination several deeply seated abscesses, some subcutaneous, others in the muscles, were found scattered over the trunk and limbs. The nasal and laryngeal mucous membranes were not affected. Only one abscess was discovered in the internal organs, and that was found in the right lung, abutting on the surface. We are informed that the coroner has refused to hold an inquest, and it may be that he is acting within his powers. It is

Digitized by Google

very clear, as a correspondent to a contemporary evening paper has pointed out, that the matter should be investigated on sanitary grounds, and we trust the local authorities will be alive to the importance of the inquiry.

AN ELOGE ON THE PROFESSION.

IN a charming volume of poems, just published under the title of "Underwoods," Robert Louis Stevenson, in dedicating his book to "a few out of many doctors who have brought me comfort and help," introduces it with the following eloquent eulogium upon our profession:—"There are men and classes of men that stand above the common herd; the soldier, the sailor, and the shepherd not unfrequently; the artist rarely; rarelier still the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilisation; and when that stage of man is done with, and only remembered to be marvelled at in history, he will be thought to have shared as little as any in the defects of the period, and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practise an art, never to those who drive a trade: discretion, tested by a hundred secrets; tact, tried by a thousand embarrassments; and, what are more important, Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sick room, and often enough, though not so often as he wishes, brings healing." Mr. Stevenson is a nephew of Dr. G. W. Balfour, Vice-President of the Royal College of Physicians of Edinburgh, so well known by his excellent work on Diseases of the Heart. He is the grandson of the eminent engineer who designed and built the Bell Rock Lighthouse, and son of the equally eminent engineer, the late Mr. Thomas Stevenson, by whom the Skerryvore Lighthouse was erected.

AN ALLEGED NEW SYMPTOM OF TUBERCULAR MENINGITIS.

THE existence of a small circle on the iris close to the pupillary border, which it completely surrounds, is the new symptom to which Dr. Skeer has drawn the attention of the Pathological Society of Chicago. When this circle commences to appear it is more or less indistinct, and resembles a whitish ribbon of somewhat transparent aspect, whose inner margin is extended almost to a level with the free border of the iris. At the end of from twelve to thirty-six hours the whole border of the iris is invaded, and has taken on a blanched tint of irregular and granular aspect. These changes, which commence simultaneously in the two eyes, are more apparent in irides of a brown colour, and they may disappear sometimes with great rapidity (so that it is necessary to examine the eyes every day), and give way to yellow-brownish rings, which increase in size as the pupil dilates. Dr. Skeer believes the changes to be tuberculous in nature and pathognomonic of tubercular meningitis.

UNOFFICIAL FORMULARY.

IN August, 1886, a committee was appointed at the British Pharmaceutical Conference to prepare a formulary of unofficial remedies. The result of the work is now before us in some eighteen pages, comprising thirty-six formulæ. The avowed intention is to bridge over the period of probation through which new remedies necessarily pass before their official recognition in the British Pharmacopœia. Hence the great object of this formulary is not so much to indicate what new drugs may be employed, but rather to suggest the most suitable solvents for those substances which have already acquired a certain reputation, to indicate what appear to be the best proportions, and also the most appropriate adjuvants. Where nauseous qualities exist, an attempt has been made to correct or disguise them. The desirability of some such "unofficial" information must have been long felt by both prescriber and dispenser, who certainly like to feel sure of the composition of their remedies. As it stands, the "unofficial formulary" is a protest against the use of remedies of secret composition. Many of the formulæ, like the *tinctura chloroformi et morphinæ* of the British Pharmacopœia may be regarded as guesses at the composition of well-known proprietary drugs. Others, on the other hand, deal with substances such as grindelia, hamamelis, hydrastis curare, convallaria coto, quillaia, &c., all of which have already gained a certain reputation, although they have not yet been allowed a place in the British Pharmacopœia. The work reflects great credit upon the committee entrusted with the duty of preparing it, and will doubtless be welcomed both by physicians and pharmacists. The only criticism we would offer at present is as to the suggestion that the formulæ of the unofficial formulary should be indicated in prescribing by adding the the letters "B.P.C." The first two letters have already such widespread and definite application that it appears a pity to disturb them, especially as the meaning of the third initial does not appear to be very clear.

CHOLERA INTELLIGENCE.

CHOLERA, although not extending rapidly in Malta, shows some signs of further activity. During the week ending September 5th, there were forty-one fresh attacks and twenty-seven deaths, and of the latter seven took place on the 5th. The disease is scattered over various parts of the island, and in all probability the real number of non-fatal attacks is not accurately known by the authorities. As yet it is almost, if not altogether, limited to the poorest portions of the native population, who are ignorant and disinclined to receive medical assistance. Amongst them there is already a great deal of destitution, and having regard to the fact that this so often becomes a strong predisposing cause of the disease, it is to be hoped that the appeals for charity which have been organised locally, and which have been submitted to the Lord Mayor of London, will receive adequate response. In Sicily there is an almost continuous daily record of deaths from the provinces of Catania and Palermo. There is also special intelligence as to a fatal outbreak at Trapani, on the extreme west coast, and at Grotte in Gergenti. The news from Naples comes but sparingly; cholera deaths, however, are still occurring there; and on the 4th inst. two deaths in Rome appear to have been properly attributed to the same cause.

MICRO-ORGANISMS IN THE ALIMENTARY TRACT.

THE interesting and valuable communication of M. Vignal to the Académie des Sciences, published in *La France Médicale*, No. 99, deserves a passing notice, for it seems to give us a glimpse into the future of physiological chemistry. M. Vignal has discovered a great number of microbes, not only in the mouth, but also in the fæcal discharges from the intestines; but the importance of this discovery does not consist either in the detection of the microbes, or in their presence in great numbers. These microbes M. Vignal has found to possess very remarkable powers of chemical metabolism, for seven of them dissolved albumen, whilst five of them caused it to swell up and become transparent. Nine of the micro-organisms could dissolve gluten, seven coagulated milk, and six dissolved casein, whilst three transformed starch into dextrin, and no less a number than nine transformed lactose into lactic acid; seven inverted crystallised sugar, and seven fermented glucose with the production of alcohol. Amongst these micro-organisms, six resisted for twenty-four hours the action of the gastric

Digitized by Google

juice at a temperature of 36° C., and the presence of spores seems to give still larger powers of indestructibility. Pancreatic juice artificially prepared and of strong digestive powers, as also bile, possessed no destructive action on these organisms. The outcome of these researches appears to be that M. Pasteur's opinion, which attributes a great *rôle* to the work of organisms in digestion, receives much support, and we may also grant the conclusion that the phenomena of digestion are far more complex than appears to be the case at first sight.

THE BISHOP OF CARLISLE ON ADVANCE IN MEDICAL SCIENCE AND ART.

IN a sermon preached in Manchester Cathedral to the members of the British Association for the Advancement of Science by the Bishop of Carlisle, a well-merited reference was made to the enormous boon conferred on suffering humanity by the progress of medical and surgical science and art during the past fifty years: "Let them think of medicine and surgery. The progress of science could not put a stop to sickness and suffering. Civilisation and artificial habits of life probably even increased and multiplied disease, but everyone must be aware how absolutely different the treatment of disease and accident was now from what it was half a century ago."

MEASLES PARALYSIS.

ALTHOUGH Landouzy, in his excellent work on the Paralysis of Acute Diseases, asserts that, without being exceptional, paralyses are less frequent with measles than with variola, yet it may be questioned whether measles does not distinguish itself, rather more frequently than is generally supposed, as the efficient cause, in certain cases, of obscure nerve disease amongst children. There are grounds also for believing that disseminated sclerosis may find a cause in measles. M. Négrié of Bordeaux has observed a case of acute ascending paralysis consecutive to measles, and he has published the clinical aspect of the case in the Bordeaux *Journal de Médecine*, No. 3 (August 21st, 1887). The child was three years old, and on the tenth day of full convalescence after measles considerable weakness was first discovered in the upper and lower limbs and in the neck muscles. Headache, pains in the limbs, and a fever of nearly 104° F. were other symptoms. The paralysis increased in degree, so that sitting was impossible; the knee jerks disappeared and the plantar reflexes appeared to be diminished. Before speaking, the child was noticed to make some jerky inspirations. Sensation and the sphincters were not affected. Paralysis of respiration seemed to be the principal cause of death, which took place five days after the *début* of the paralytic symptoms. Négrié does not make any reference to the possibility of the presence of diphtheria in the case in question.

A COMPENSATION CASE.

A DIFFICULTY has arisen at Newton-Poppleford as to whether compensation can be given by the St. Thomas rural sanitary authority in the case in which bedding and clothing were destroyed in an instance of alleged fatal cholera, the destruction having been carried out on the advice of Dr. Pullin, a private medical practitioner. The widow is by no means well off, the action taken was adopted in the interests of public health, the promptitude of Dr. Pullin has been recognised by all, and yet the authority decline to give the compensation asked for. It is quite true that, according to the strict letter of the law, "the authority" must direct the destruction, and it may then "give compensation for the same." But it is perfectly well known that since the authority, as such, only meet at distant intervals, the provision would be perfectly useless if their actual assent were always required. The reasonable attitude for them to assume would be to adopt the action taken by Dr. Pullin on their behalf and pay the compensation. No one would ever interfere or find fault, and an equitable termination would be brought about. We understand that the Local Government Board have been communicated with, but except in the case of a surcharge we do not well see how they can help the authority. The intention of the clause clearly is that the authority should act as it sees fit in the matter.

HYSTERICAL RELIGION.

OF course nothing disrespectful to the idea of a truly religious sentiment must be inferred from our use of the phrase *hysterical religion*. What we mean to designate by that term is religious fanaticism essentially emotional in its nature, and probably also in its origin. "Jumping," "Shaking," and the like are distinctly morbid disturbances brought about by abandonment of the controlling will and judgment to the seasory impulses or the passions. Weak minds are supposed to be more prone than those which are normally robust to make this surrender of self-control, but, as a matter of fact, it may be, and doubtless is, not unfrequently made by the strongest of intellectual organisms under the influence of such strong "feeling" as may readily be produced by overtaxing the higher cerebral centres. The wondrously complex mental apparatus is easily thrown out of working order, and it is not in the least surprising to find the more delicately organised and sensitive machinery of mind work so disabled. It follows upon this consideration that the subjects of "hysterical" disturbance in connexion with religious thought and emotion are rather to be pitied than blamed for their vagaries. Nor are we prepared to say that, however much the existence of distinctly hysterical religions may be regretted, they ought to be put down by law. At the same time it is clearly in the interests of public health and sanity that they should be adequately controlled, and we cannot help thinking that the young girls who hop in "glory holes" ought to be placed under some kind of supervision, if only that they may not be allowed to fall victims to the men "full of devils" who are *not* turned out of the places of "worship" where these decidedly undesirable orgies are held.

PEAT MOSS AS A DEODORISER.

DR. D. M. USPENSKI, in a preliminary note in the *Vrach*, describes a number of bacteriological and other observations he has made on a kind of peat moss belonging to the sphagni, which is indigenous in many parts of Russia and Siberia, and which is used with considerable success in the form of coarse powder for disinfecting cesspools and privies in Warsaw, Riga, and other towns. It is found that about four ounces sprinkled over an ordinary stool is sufficient to deodorise and dry it, so that the receptacle can be emptied and cleaned at proper intervals without any unpleasantness arising. This substance seems to have a wonderful power of absorbing moisture, for it was found by experiment that a pound of it which already contained 25 per cent. of water was capable of absorbing no less than seven pounds and a half more water. When added to fæcal matter in the proportion of 10 per cent. by weight, it changes it into an almost dry mass of an earthy appearance, devoid of smell and easy to remove. A hundred pounds of the powdered moss will absorb 1438 litres of ammonia. The dry mass obtained by the action of the moss on fæces, on being analysed by Mr. Miltser, was found to contain from 2·38 to 2·66 per cent. of nitrogen, and from 0·96 to 1·15 per cent. of phosphoric acid, and of course formed a very

Digitized by Google

valuable manure. The powder as received contained 23·9 per cent. of water and 5·38 per cent. of ash, and without any preliminary drying they absorbed fourteen times their own weight of water. Bacteriological experiments proved that the moss has a great capacity for diminishing micro-organisms of various kinds. If this substance can be easily and cheaply obtained, it would appear to offer advantages over the dry earth we are accustomed to use, and in large towns would doubtless prove very valuable.

PROFESSOR NOTHNAGEL.

A HOLIDAY contributor writes:—"Miraculous is scarcely too strong a description of the escape this illustrious physician had the other night on the Moskow-Smolensk Railway. On the summons of M. Poljakow, manager of the Moscow network, he had gone to a consultation in that city, and, his professional mission over, he had entered a sleeping car on his homeward journey on the night of Aug. 20th. He had barely settled down in bed when he had occasion to leave his *coupé*, and, after making his way along the passage, opened the wrong door and fell out upon the metals. How he alighted without further injury than a slight bruise on one of the temples and another on the foot remains a mystery even to himself. As it was, his position was eminently a critical one. Bareheaded and in the scantiest night gear, he found himself on a dark rainy night on the lonely line—no one in the train, it seems, having been aware of his fall. With great difficulty and discomfort, and in the midst of a storm, he reached the house of the nearest guardian of the line, and was by him accompanied to the Iwanowka station; thence he got by train to Dünaburg, where the station-master gave up to him his clothes and travelling effects, as well as his pocket-book containing more than 10,000 roubles, also left behind him in the carriage. Science and suffering humanity may well congratulate themselves on the special providence that seems to have safeguarded their distinguished votary."

THE SPREAD OF THE TUBERCLE BACILLUS BY FLIES.

IN a communication made to the Académie des Sciences by MM. Spillman and Haushalter, and recorded in *La Semaine Médicale*, the question of the spread of the tubercle bacillus by means of the common house fly is considered. The authors state that they have seen flies enter the spittoons containing the sputum of phthisical patients; they were then caught and placed in a bell jar. On the following day several of these were dead. Examination of the abdominal contents and the excrement of these flies on the inside of the jar showed the presence of many tubercle bacilli. The authors point out the wide dissemination of the disease which may take place in this way, and recommend as a preventive the employment of covers with a small opening.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—M. Giraud-Teulon, member of the French Academy of Medicine. He was at first a student in the École Polytechnique and the École d'Application at Metz and afterwards took up the study of medicine. From his admission to the Doctorate in 1848 to his death he occupied himself with investigations connected with medical physics, the mechanism of respiration and locomotion (his views differing greatly from those of M. Marey), the effect of the atmospheric pressure on the serous cavities, and, finally, a large number of questions concerning ophthalmology. He wrote important memoirs on the differences between the arterial and venous vessels in the retina, and the signs of grave affections of nutrition characterised by subsequent lesions of the membranes of the eye and of the lens. He invented several instruments, including a binocular ophthalmoscope.—Dr. Friedrich Fuhrmann, *Sanitätsrath* in Görlitz.—Dr. Victor Friedländer, of Breslau.—Surgeon-General Heinrich Christoph Niese, who succeeded Langenbeck as Staff Surgeon-General of the Schleswig Holstein Army.

A WANT IN MANCHESTER.

A CORRESPONDENT informs us that great inconvenience is experienced by strangers visiting Manchester during the meeting of the British Association from a want of public urinals. This is a real inconvenience in many other places as well as Manchester, and the time has come when provision should be made in this respect for both males and females. We have often advocated this in our pages. At the Section rooms ample provision has been made, but on Sunday and after 3 o'clock on other days these are closed to the members, and this has been severely felt in the absence of a sufficient public provision. The secluded gateways leading to one or other of the great warehouses in which Manchester abounds are, judging from the odour thereabouts, made to supply the want.

REFLEX NEUROSES FROM CONSTIPATION.

BESIDES disturbances of the circulation, and especially palpitation, irregularity of pulse, and vertigo, which may be attributed to excitation of the cardiac branches of the great sympathetic, Kisch believes that rebellious hemicrania often recognises no other cause than constipation. Certain kinds of sciatic neuralgia, and lumbo-abdominal pains, or ovarian aches, and even neuralgiæ of the fifth pair, have been ascribed to habitual constipation. Although Kisch has collected forty-eight cases in which cessation of constipation was followed by relief from diverse and chronic neuralgiæ, we may well question whether intestinal sluggishness was the *causa causans* of the various neuralgiæ. The alteration of even one element cannot be effected without the production of more than one result.

EMPTY HOUSES.

A MEDICAL CORRESPONDENT, writing to the daily press, calls attention to the risks to householders resulting from the evaporation of water from traps, occurring during a period when the house is unoccupied, and states that it has fallen to his lot to see more than one outbreak of sore throat, which he believes is caused by this circumstance. It may be hoped that the usual house cleaning, which necessitates the occupation of the house immediately before the return of its owners, is for them a safeguard; but the subject is well worth the attention of householders, in the interest of caretakers as well as of themselves, and the careful charging of traps and the thorough ventilation of houses are necessary wherever they have been left uninhabited during any period of time.

INFLUENCE OF COMMON SALT ON GASTRIC SECRETION.

DR. REICHMAN describes, in the *Gazeta Lekarski*, his experiments on the effect of the ingestion of chloride of sodium on the secretion of gastric juice. The conclusions he arrives at are that it has not a stimulating action on the secretion, but that it diminishes the acidity of the gastric juice even in solutions containing less than 5 per cent. of the salt. This diminution of the acid reaction of the gastric juice depends chiefly on transudation from the bloodvessels of the mucous membrane of the stomach, and perhaps, to some extent, on an increased secretion of mucus.

THE ILLNESS OF THE CROWN PRINCE.

ON Wednesday last at Balmoral Her Majesty conferred the honour of knighthood on Dr. Morell Mackenzie in recognition of the professional services recently rendered by him to the Crown Prince.

THE MOXON MEMORIAL.

WE are requested to state that the sum at the disposal of the committee of the Moxon Memorial amounts to £605 16*s.* 10*d.*, and that early in October a meeting will be held to determine the proportion in which it is to be assigned to the Royal College of Physicians and to Guy's Hospital, for their respective memorials.

ACCOMMODATION FOR SCARLET FEVER PATIENTS.

IT is well at this moment to remind the public of the admirable accommodation, on moderate terms, to be had at the London Fever Hospital, Liverpool-road. We learn that there are at present forty beds vacant in the institution.

FOREIGN UNIVERSITY INTELLIGENCE.

Dorpat.—Dr. Dragendorff, Professor of Pharmacy, has been elected Corresponding Member of the Belgian Academy of Sciences.

Havana.—The Spanish Government has issued a number of new regulations which will improve the education given in the Cuban capital and assimilate the course of study to that given in Madrid.

Warsaw.—Dr. K. P. Kowalkowski has been appointed Extraordinary Professor of Hygiene.

RETIRED Deputy Surgeon-General J. R. Jackson, I.M.D., was fatally wounded on the 1st inst. while shooting on a Scotch moor. A friend who accompanied him was loading a gun, when it accidentally discharged, and the contents lodged in Dr. Jackson's side, death ensuing in about a quarter of an hour. The deceased, who was fifty-five years of age, leaves a widow and two children.

THE annual report of the Police Committee of the Tweed Commissioners, recently issued, states that this year 9521 diseased salmon, grilse, and trout have been taken out of the river. Professor Greenfield of Edinburgh is, we understand, investigating the nature of the micro-organisms in the river water in connexion with the salmon disease.

DR. BILLROTH continues to make satisfactory progress towards complete recovery. He is now able to ascend the Schafberg on foot (some 6500 feet above the sea level, and commanding "le plus beau panorama d'Allemagne"), and to return, also on foot, to his pleasant quarters on the Wolfgang-See, without feeling over-tired.

IT has been decided by the Brighton and Hove Intercepting and Outfall Sewers Board that, subject to the consent of the Brighton Town Council and the Hove Commissioners, a sum of £9000 shall be spent on the extension of the outlet of the intercepting sewer, so as to carry it 500 feet further seawards.

THE Office of the Army Medical Department has been removed to No. 2, Victoria-street, Westminster, S.W.

IT is rumoured that the Emperor of Austria intends to confer a decoration of a high class upon M. Pasteur.

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

(FROM OUR SPECIAL CORRESPONDENTS.)

Per Anglo-American Telegraph Company.

ON Monday, the 5th inst., the ninth International Medical Congress opened under most favourable auspices at Albaugh's Opera House, Washington. The building was crowded with members of the medical profession from all parts of the world. A short speech of welcome was delivered by President Cleveland, who at the close of his address was rewarded with enthusiastic applause. After the election of a president and officers of the Congress, Mr. Bayard, Secretary of State, gave an eloquent address, in the course of which he pointed out that the development of America was due to the non-interference of the Government with natural advancement in this democratic Republic. The brotherhood of science well realised the importance of such non-interference, none more than practitioners of medicine and surgery. He welcomed the members of the Congress as the guardians of the health of nations. In medicine he recognised the noblest school of human usefulness; in the presence of such development as it is at present making, he recognised the means of cure, of the amelioration of suffering, and the prolongation of human existence. In the endeavour to discover the true principles which make life worth living, one must, he said, acknowledge the debt owing to those whose chief reward is the still small voice of approving conscience. The following responded to Mr. Bayard's address:—Dr. Lloyd, Deputy Inspector-General of Hospitals and Fleets, for Great Britain; Dr. Lefort for France, Senator Semmola for Italy, Dr. Unna for Germany, and Dr. Reyber for Russia.

Dr. Davis (Chicago), President of the Congress, then delivered his address, which is printed in full in another part of our present issue.

Dr. Alvarado, representing the Mexican Government, then read a paper on the Pathogenesis of Yellow Fever.

Professor Geikil (Toronto) read a paper on Pneumonia, in which he described pneumonia as being met with in all parts of Canada, no district being exempt from the disease.

During the delivery of the President's address and the reading of these papers there was a large audience, and at the close an animated discussion, in which many of those present joined, took place.

In the Section of *Surgery*, the President, Dr. Briggs of Nashville, delivered his address, in the course of which he entered at length into Modern Surgery of the Abdomen with Antiseptic Appliances.

Dr. Parker (Chicago) read a paper on the Study of Gunshot Wounds of the Intestines. He discussed and showed examples of many cases in which after death it was conclusively proved that an abdominal operation would have saved the life of the sufferer, and concluded by earnestly advocating, as the result of his experience, the early performance of operation in cases of such a nature.

Dr. Senn read a paper on Experimental Intestinal Surgery.

In the Section of *Obstetrics*, the President (Dr. Miller, Chicago) delivered an address, the three chief topics upon which he touched being Craniotomy, the cultivation of skill in Diagnosing Extra-uterine Pregnancy, and the rendering of the Puerperal State Aseptic without danger from the use of toxic substances. He expressed his belief that in future craniotomy would only be exercised in most unusual circumstances, and that the life of the child would be saved with but little danger to the mother. He advocated the destruction of the fœtus by electricity in extra-uterine fœtation to prevent rupture.

A paper on the Value of Contractions of the Uterus in Diagnosing Pregnancy, by Dr. Braxton Hicks (London), was, in the author's absence, read by Professor Earle, Chicago. During the whole period of pregnancy, contractions, Dr. Hicks stated, occur at short intervals, and as they can be felt by palpation, these contractions are useful as a means of distinguishing tumours from pregnancy. It is physiologically important to empty the uterine veins, as constant relations exist between the carbonised blood in the veins and the contractions and movements of the fœtus.—

Digitized by Google

In the discussion which followed, Professor Simpson, of Edinburgh, confirmed the importance of these contractions as an aid in the diagnosis of pregnancy. Professor King and Professor Charpentier, of Paris, also took part.

Dr. MacCullum (Montreal) read a paper on Vicarious Menstruation.

Professor Lazarewitch (St. Petersburg) and Dr. Stewart (Philadelphia) showed improved forceps, which were criticised severely by Professor Opie, of Boston.

In the Section of *Public and International Hygiene*, the President, Dr. Joseph Jones, of New Orleans, read a paper on Public Hygiene, in which he sketched the progress of sanitation, and discussed modern sanitation in its threefold aspect—viz., domestic, public, and international. He indicated the importance of the duty of personal and domestic hygiene, the duty of municipal and other health authorities, and, lastly, the importance of nations comparing their methods of sanitation, and informing one another on the principles of hygiene.

The Section of *Vital Statistics* was well attended, and the address much applauded.

In the Section of *Diseases of Children*, papers were read by the President, Dr. Smith, of New York, and by Dr. Jules Simon, of Paris (who was not present in person), on Cerebral Irritation in Children. He referred to forms not due to heredity, congenital syphilis, &c., but to insanitary and exciting surroundings.

Professor Sayre (New York) read a paper on the Deleterious Results of Narrow Prepuce and Adhesions.

Dr. De Saint-Germain (Paris) in a short paper advocated igni-puncture of the tonsils by cautery in place of tonsillotomy. He recommended a puncture of three-eighths of an inch repeated each week, and stated that such procedure would almost invariably bring about a cure in a month.

Most of the eighteen Sections are well attended, especially the Gynæcological and Pathological ones.

In the *Ophthalmological* Section good discussions took place on a paper by Dr. Mooren (Germany) on Eye Troubles: their relation to Occipital Disease.

A paper was read by Dr. Connor (Detroit) on Hot Water Treatment in Eye Diseases, the discussion on which brought out various methods of applying heat to the eye.—Dr. Thompson (Indianapolis) advocated slippery elm poultice; Dr. Keyser, steam; Mr. Henry Power (London), dry meal and dry hops, but never steam.—Dr. Abadie (Paris) said he had a very poor opinion of hot water or heat unless there was much pain. In his practice he relied on more active medicaments, such as iodoform, morphia, and leeches, combined with judicious internal treatment.

In the evening a large *soirée* took place in the Pension Building. Upwards of six thousand persons were present, the admission being entirely unrestricted. The decorations in the great hall were very pretty. Much bunting was displayed, the American flag predominating; flags of all nations were used.

A sumptuous banquet by American medical editors to foreign editors and distinguished guests was given at Rigg's House. One hundred and fifty covers were laid. The decorations were superb, no less than 3000 roses being used in the floral ornamentation.

On the 6th inst. a general address by Dr. Austin Flint (New York) was delivered on Fever: its Causes, Mechanism, and Rational Treatment. There was a large audience, and the Opera House was well filled. Dr. Flint observed that fevers were due to a certain specific cause, probably micro-organisms. As we were not able to destroy these, we must be content to moderate their action and sustain the vital powers. The production of animal heat involves oxidation of part of the organism, or of articles of food represented by formation and discharge of nitrogenised matters. As regards its relations to general nutrition and the production of animal heat, water formed in the body by the process of oxidation should be considered excrementitious. Fever might be defined as a condition of excessive production of heat involving defective nutrition or inanition, an excessive production and discharge of nitrogenised excrementitious matters and carbonic acid with waste and degeneration of tissues, and partial or complete suppression of production and discharge of water. The active symptoms in fever, apart from complications and accidents, are proportionate to the elevation of temperature. These conditions must be ameliorated by treatment chiefly directed towards the reduction of temperature, as by the abstraction of heat by cold or the use of antipyretics, which without affecting the special cause improves the symptoms. During the period of inanition the consumption of the tissues in the production of animal heat is in a great measure saved by the increased production and excretion of water in fever. The effects of inanition are manifested by the destruction and degeneration of tissues, which are intensified by deficient formation and excretion of water. Alimentation is difficult mainly on account of the derangement of the digestive organs. This may be met by the administration of food easily digested or already partially digested. Hydro-carbons are important factors in the production of animal heat. Alcohol is promptly oxidised, and is capable of absorption without digestion. So far as it is oxidised in the body, alcohol in fevers supplies matter consumed in the production of heat, and saves destruction of tissue. The introduction of matter thus consumed diminishes pyrexia. As oxidative alcohol involves the formation of water and limits tissue destruction, its action tends to restore normal heat production processes. The aim of treatment is, Dr. Flint observed, to limit and reduce pyrexia by direct or indirect means, to limit the destruction of tissue and provide for its repair, and by alimentation to provide matters for consumption in the abnormal production of heat, and thus place the system in the most favourable conditions for recuperation.

In the evening a reception was held by the President of the United States and Mrs. Cleveland at the White House from 8 to 10. The Corcoran Art Museum was also open for members of the Congress and ladies. The scene was an animated one, the people and costumes being most diverse.

The Section of *Medicine* was chiefly occupied in discussing the question of vaccination.

Dr. Korosi (Buda Pesth) read a paper on the Preventive Power of Vaccination, and combated all objections from statistics, &c, from his own observations.

Dr. Whitmarsh (England) read a paper on Vaccination and Pasteur's Treatment, which gave rise to an animated discussion, in the course of which Dr. Leale deprecated alarming patients who had been bitten.—Dr. Welch gave a strong argument in support of vaccination by the comparative immunity from the disease enjoyed by hospital *employés*, and the fact that there are few vaccinated patients—under 5 per cent.—received into small-pox hospitals, and these rarely died. The danger of syphilis was, he remarked, remote, and erysipelas usually arose from carelessness.

In the *Surgical* Section a paper was read by Dr. Homans (Boston) on 384 Laparotomies for various diseases which he had met in his own practice. Ventral hernia occurred in 10 per cent. of the cases operated upon under the spray and bichloride of mercury. The fatal cases often resulted from trifling faults of the operator. The removal of the ovaries and tubes without objective symptoms was most reprehensible. Dr. Matthews (Louisville), in a paper entitled "When is Colotomy Justifiable?" said that the operation should not be performed when the stricture is three inches and a half above the anus, nor for cancer of the lower bowel, nor for tumours which closed the bowel, nor for congenital occlusion of the rectum when the rectum is occluded above three inches up. Colotomy for cancer does not prolong life. In the discussion which followed, Dr. Benton (England), Dr. O'Neal, Dr. Anthony, and others joined. The discussion showed most members to be in favour of operation in malignant disease for the relief of pain.

In the Section on *Diseases of Children*, papers were read on the Milk Supply of Cities, by Dr. Edson (New York); on the Nutrition of Infants, by Professor Leeds (Hoboken); and on the Use of Cows' Milk for Infants, by Professor Vaughan (Michigan). Professor Vaughan's paper was a most interesting one, and provoked much discussion. He said that cows' milk for infants must be from healthy animals, and must be well preserved from putrefaction both before and after it is taken into the child's stomach, a thing which is impossible if the infant is over-fed or breathing a polluted atmosphere.

Several papers on Intubation of the Larynx were also read. One by Dr. O'Dwyer (New York) was of considerable length. Comparing the results of tracheotomy *versus* intubation, he said that the question is—Which can be performed or permitted? With most medical men tracheotomy was never popular, and it is performed only in a minority of croupous cases, owing to the repugnance of the patient's friends. It is not done in one-fourth of the fatal cases in New York. The true mortality after tracheotomy is not known, as many fatal cases are never published. He concluded by strongly advocating intubation.

Digitized by Google

Dr. Waxham also read a paper on the same subject, in which he strongly endorsed the same views.

This Section was a very popular one, and the papers read in it and the accompanying discussions have excited considerable interest.

In the Section of *Obstetrics*, a paper was read by Professor Cameron (Montreal) on the Influence of Leukæmia in Pregnancy. There were, he said, but few cases reported where leukæmia occurred during pregnancy, and none where a leukæmic woman became pregnant. He cited a case of a lukæmic woman who, becoming pregnant, produced children with leukæmic tendencies.

A paper was read by Professor Charpentier (Paris) on Uræmia. Injections of urea into pregnant animals, he observed, caused the death of the fœtus prior to that of the parent, and from this it may be concluded that the fœtus eliminates urea more slowly than the mother. Professor Lusk said that the paper threw light on an important subject, which it was desirable should be settled. He doubted the importance of urea, because cases were frequently met with in which an excess of urea was accompanied either by the death of the fœtus or the occurrence of dangerous symptoms in the mother. Dr. Maccullum (Montreal) pointed out the desirability of inducing premature labour in cases of albuminuria, if urea was dangerous to the fœtus.

A paper was read by Professor Simpson (Edinburgh) on Uniformity in Obstetrical Nomenclature. The communication embodied the results of the inquiries made by the committee appointed at the London International Congress.

Professor Lusk read a paper on the Prognosis of Cæsarean Section. He condemned craniotomy whilst the child was living and viable, and advocated early section by skilled operators.

A paper on the same subject was also contributed by Dr. Saenger (Leipsic).

In the Section on *Hygiene* a paper was read by Dr. Day (Batonrouge) on the Effects of an Overflow of the Mississipi. It contained the result of inquiries from 500 physicians in the South, which showed that, as a rule, river overflows were injurious to the public health, the evil effects being minimised by good drainage.

A paper was read by Dr. Grant Bey (Cairo) on the Hygiene of Modern Egypt.

Dr. Leighton (Newhaven), in a paper on the Place of Sanitary Science in Education, advocated a more definite position in teaching schools, colleges, &c., for the study of popular literature, and assistance from the press and pulpit.

The *Military* and *Ophthalmic* Sections were very busy. In the former papers on Gunshot Wounds were read by Drs. Hyde and James, which led to an animated discussion on explosive bullets. The United States is not yet, it seems, in accord with Europe on this question, but no such bullets have actually been used since 1863. Dr. Smith wished to bring the subject under the notice of the Congress and the President of the United States.

Surgeon-Major Langridge read a paper on Sunstroke. He cited his Indian experiences, and described how soldiers could best withstand heat. Drs. Marston, Goodman, Sherwood, Collins, and others, took part in the discussion. A paper by Sir Thomas Longmore, on Field Dressings, was read by Dr. Marston.

In the *Ophthalmological* Section, Mr. H. Power (England) read a paper on Microbes in the Development of Eye Diseases, in which he pointed out that whilst it was easy to recognise pathogenic cocci and prevent their entrance, it was difficult to destroy them when once in. He advocated the use of boric acid. Many members took part in the discussion which followed.

Professor Mooren (Dusseldorf) contributed a paper on the Methods of Extraction of Cataract. He had had 5000 extractions, and was of opinion that iridectomy should be done always at the time of operation.

Dr. Galezowski (Paris) also read a paper on the same subject.

On the 7th inst. an unpleasant incident occurred between two Italian delegates. Professor Durante claimed to be sent by Government, but had to give place to Dr. Semmola, who is a senator in the Italian Parliament. The affair was, however, satisfactorily adjusted through the kindly and opportune mediation of Dr. Hamilton. At the conclusion of Dr. Semmola's address quite a dramatic scene took place on the stage of the Opera House, when the two delegates publicly shook hands. Dr. Semmola's address was delivered with fine effect in French. He said that the object of medicine was to cure disease; if there were no ills there would be no doctors. To cure diseases we must know the causes which produced them, the external causes visible and tangible, and we must discover the internal ones. It was the aim of medical science to solve this problem, and for its solution we must employ the true method for solving all problems—viz., the experimental method. Before the experimental method was known doctors lost themselves in fantastic speculations, and it was only after the discovery of the experimental method that serious study began its marvellous progress. Physiology made light of experimental methods when studied under morbid condition, but doctors wanted to hurry on because they wished to cure the sick; but it is impossible to apply the experimental method and at the same time to go fast. If medicine be a science, we must not leave the experimental method, otherwise, like the labours of Sisyphus, there can be nothing but renovations, errors, loss of time. Some errors are repeated without knowing it. The chief error of to-day is that of bacteriology being considered the key to all pathology. Bacteriology should be studied because it teaches what exists in the microscopical world. This world is filled with enemies to mankind. We drink millions of microbes in our water, we respire millions in the air we inhale. Sometimes these microbes affect us, sometimes killing in a few hours. It is in cases like this, with our duty to cure the sick under our care, that we should go slowly; because if before there has been a careful demonstration we attempt to deduce a remedy, we are in danger of doing harm instead of curing. This is the great harm modern bacteriology does doctors. It has at once been concluded that microbes are the cause of disease, whereas in many cases microbes are but the effects of disease. We ought to reproduce the disease artificially by means of microbes before definitely concluding that they are the cause. The experiments which have been made do not give satisfactory results, except in the instances of carbuncle and tuberculosis. To conclude hastily that this or that microbe existing in such and such disease is the cause of it is to ignore the experimental method of demonstration. In this case of the experimental method the demands would be complicated, because not only have we to know that microbes existed, but we would have to know what the condition of the blood was which is necessary for the culture of that particular microbe. Science tells us that for the present the problem cannot be solved. We know very little of the normal condition of the blood. Biological chemistry is still in its infancy; man cannot separate himself from these millions of parasites among whom he lives. Bacteriology may guide us in the cure of disease, but we must not only learn all that is possible of the microbe itself; but, more important than all, we must ascertain all that is possible respecting the conditions of the field of culture. But science of the present day knows nothing of the conditions of these fields of culture in living organisms, and it is thus evident that in its present condition bacteriology cannot guide us in the treatment of internal diseases. The followers of the older school of medicine used to talk of organic dispositions and tendencies to such and such diseases. This language has no meaning. When bacteriology speaks of a need for special fields of culture, it says the same thing, because we do not know of what the field of culture consists; therefore it cannot be called a science, because science is never composed of unknown things. It goes from the known to the unknown. Science must indicate perfectly the conditions of the phenomena of disease, and then only can we find the remedy to correspond. Medicine must advance like physiology, chemistry, and physics, and proceed by way of experiments and demonstrated facts. Look at the progress made by physics and chemistry as applied to industries. Look at the telegraph, telephone, steam-engine, photograph, &c. The experiments which led to these results were not composed of unknown things and hypotheses, but were made up of a chain of experiments, each link of which was perfectly forged and welded. Thus there was no weak link in the chain, and phenomena reduced by the laws of science at man's disposal can be reproduced at his pleasure. But man does not command nature; he learns her laws and respects them. If he supposes fact instead of demonstrating it, the phenomena are not reproduced when he resorts to hypotheses. The power of man disappears if nature's laws are not respected; the telephone does not work, the electric light does not flash, the steam-engine stops. The doctor,

Digitized by Google

then, is the only one who pretends to become the master of nature without knowing her laws." Referring, again, to the failure of medicine to follow up a discovery in a scientific way, with thorough research and demonstration, and to its tendency to accept conclusions quickly, Professor Semmola said modern bacteriology may lead the way to a most fruitful field of inquiry in the future, but at present it produced no practical results in the cure of internal diseases. It has not been demonstrated in what measure microbes are the cause of diseases, and he therefore hoped that the younger generation would continue experimental researches with the thoroughness of method which the great masters have transmitted to us; they must renounce preconceived ideas of medicine, and interrogate nature without torturing her; scientific independence must be preserved, and they must not proceed without measuring their steps. He trusted that his desire for scientific independence in such researches would be echoed in this land of independence. At the conclusion of the address, a vote of thanks to Dr. Semmola was supported by several delegates on the stage, who made very complimentary reference to the value and interest of the address.

Up to Wednesday at noon the number of members registered at the offices of the Congress was 2600. About 300 of these are foreign, all European countries being represented, France, Germany, Russia, Italy, the Balkan provinces, &c. England sends a large contingent—Seaton, Marston, Power, Langdon Down, Isambard Owen, Pavy, Savage, West, G. Hewitt (London), Simpson (Edinburgh), Chavasse (Birmingham), L. Roberts (Manchester), Tomkins (Leicester), Tate (Nottingham), Taylor (Liverpool), Cunningham (Cambridge), and others. The total number of members present exceeds the record of former Congresses, but the bearers of many well-known European names are conspicuous by their absence, as also are some Americans. The meeting is an undoubted success, but many of the leading men, especially those residing in New York, are absent. Much hospitality is shown to foreigners by the citizens—garden parties, banquets, receptions, &c. Visitors are to be taken to Niagara free of expense. On the 8th inst. a banquet is to be given by Washington city. The weather is glorious, and the heat moderate. The organisation of the Congress is scarcely perfect in some respects, and many lessons might have been learned from former similar meetings. The United States Congress is not sitting, consequently many of the leading citizens are away for the summer. Their absence has a tendency to limit private hospitality, but much difficulty has been experienced even now in the dull season of the year to provide accommodation for the influx of some 4000 visitors from the most remote parts of America, South, North, Canada, &c. Washington is a beautiful city, and all the sights, Government buildings, &c., are open for inspection by members of the Congress.

THE INTERNATIONAL CONGRESS OF HYGIENE.

THE final touches have now been given to the programme of this gathering. The opening ceremony will take place on September 26th, at 11 A.M., in the great hall of the Musikverein, when the Crown Prince Rudolf, "the protector of the Congress," will bid its members welcome in the name of the Kaiser. On the evening of the 28th, again in the name of the Kaiser, the members will be formally received in the Hofburg. Their number is now 1410, representing, as we have already shown, nearly every civilised state in the world, and every considerable association concerned directly or remotely in public hygiene. This number is likely to be still further increased, as the Congress extends its hospitality up to the close of its sittings, a hospitality which includes the gift of the very valuable publications dealing with all the topics to be discussed. The Vienna town council has shown itself fully alive to the importance of the occasion, and is taking every care that no former seat of Congress, neither Paris, nor Brussels, nor Geneva, nor for that matter the best traditions of the magnificent princes of the Venetian and Florentine Republics, shall be quoted to their disadvantage. The town hall is itself, as few such buildings can, to festive celebrations and to the worthy reception of distinguished guests. The volunteer Rettungsgesellschaft (Preservation Society) of the city will exhibit on the Trabrennplatz (racecourse) their preserving apparatus and sanitary *matériel*. The municipality of the various guilds and mercantile firms, to say nothing of neighbouring landed proprietors, in contributing to the funds of the Congress, has been munificent. The surplus, after the defrayal of all expenses, will be applied, as already stated, to the erection of an institution for perfecting hygienic manufacture in all its aspects, for which suggestions and criticisms are freely invited from members of the Congress.

As we write, the announcement reaches us that, by command of the Kaiser, a gala representation, in honour of the members of the Congress, will be enacted in the Court Opera House, which for that occasion will be placed at their special disposition. The performance will take place on Tuesday, Sept. 27th, and will conclude, appropriately, with the ballet of "Excelsior."

THEATRE FIRES.

THE Home Secretary is reported to have said on Tuesday night, in answer to Dr. Tanner: "Outside the metropolitan area there is no power in any Government Department or in any local authority to inspect theatres or insist on structural alterations, except as a condition of licensing the theatre in the first instance, except possibly under local Acts. Within the metropolitan area the Metropolitan Board of Works have sufficient power to enforce any precautions which may be necessary, and have largely acted on those powers."

In this connexion the following extracts from the last report of the Metropolitan Board will be found of interest:—

"The Board's jurisdiction over new theatres, and over music-halls containing an area for the accommodation of the public of not less than 500 square feet, is defined by the 12th section of the Metropolis Management and Building Acts Amendment Act, 1878, which prohibits the opening of any such place of public entertainment without a certificate from the Board to the effect that it was, at the time of its completion, in accordance with the regulations which the Board was empowered by the Act to make for the protection from fire of these buildings. The regulations now in force were made on May 2nd, 1879. The applicant for a certificate is required, in the first instance, to submit drawings of the proposed new building for the inspection of the Board, and, in the event of these being found satisfactory, they are conditionally approved; but the sealed certificate is not issued until the building has been completed, in accordance with the approved drawings, to the satisfaction of the Board.

"The 11th section of the Metropolis Management and Building Acts Amendment Act of 1878 gives the Board a limited jurisdiction over the theatres and larger music-halls which were in use at the passing of the Act, on July 22nd, 1878. The Board can take action with respect to any such building when it appears that the place is so defective in its structure that special danger from fire may result to the public frequenting the same, and that the structural defects can be remedied at a moderate expenditure. The consent of the Lord Chamberlain or of the Secretary of State, as the case may be, must be obtained before any notice can be served by the Board upon the owner. Having obtained this consent, the Board may serve the owner with notice requiring him to make such alterations in the building as may be necessary to remedy the defects within a reasonable time, to be mentioned in the notice. In default of compliance with the notice, the owner becomes liable to a penalty of £50, and a continuing penalty of £5 a day. Within fourteen days of the receipt of the notice the owner may appeal to an arbitrator, to be appointed by the First Commissioner of Works. The arbitrator, whose decision is final, may make such order as he thinks fit, and direct by whom, and in what proportion, the costs of the arbitration are to be paid.

"The theatres within the jurisdiction of the Board, which were inspected by the chief officer of the fire brigade in order to ascertain their actual condition in respect of security from fire, were forty-one in number; and it was stated in the last report that the whole of these, with the exception of those that had been closed, had been put into a satisfactory structural condition."

This is all very well so far as it goes, but if peril arises, as seems to have been the case in the sad fatality at Exeter, from the improper disposition of scenery not at the moment in use, how does an annual inspection by an officer of the fire brigade afford any protection against this risk?

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5166 births and 3348 deaths were registered during the week ending September 3rd. The annual rate of mortality in these towns, which had declined from 23·7 to 23·3 per 1000 in the preceding three weeks, further fell last week to 18·9. During the first nine weeks of the current quarter the death-rate in these towns averaged 21·7 per 1000, and was 0·5 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·3 in Huddersfield, 15·6 in Bristol, 16·6 in London, and 17·2 in Derby. The rates in the other towns ranged upwards to 25·0 in Manchester, 25·8 in Wolverhampton, 25·9 in Blackburn, and 29·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding five weeks from 1301 to 925, further fell last week to 792; they included 500 from diarrhœa, 84 from scarlet fever, 76 from whooping-cough, 49 from measles, 47 from "fever" (principally enteric), 31 from diphtheria, and 5 from small-pox. These diseases caused the lowest death-rates last week in Bristol and Huddersfield, and the highest in Plymouth, Wolverhampton, and Oldham. Diarrhœa caused the greatest mortality in Brighton, Plymouth, Bolton, and Wolverhampton; measles in Birkenhead and Oldham; scarlet fever in Blackburn, Bolton, and Oldham; and "fever" in Leicester, Oldham, and Portsmouth. Of the 31 deaths from diphtheria in the twenty-eight towns, 20 occurred in London, 3 in Newcastle-upon-Tyne, and 2 in Hull. Small-pox caused 5 deaths in Sheffield, but not one in Greater London or in any of the twenty-six other large provincial towns. Only 3 cases of small-pox were under treatment on Saturday last in the Metropolitan Asylum hospitals receiving cases of this disease, of which one was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 178 and 160 in the preceding two weeks, rose again last week to 169, and were within 1 of the corrected average. The causes of 62, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Wolverhampton, Bradford, Sunderland, and in four other smaller towns. The largest proportions of uncertified deaths were recorded in Preston, Halifax, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·6 and 18·7 per 1000 in the preceding two weeks, declined again to 18·5 in the week ending September 3rd; this rate was slightly below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·1 and 16·2 in Leith and Perth, to 21·4 in Dundee and 26·5 in Paisley. The 463 deaths in the eight towns last week were within 3 of the number in the preceding week, and included 39 which were referred to diarrhœa, 31 to whooping-cough, 18 to scarlet fever, 12 to "fever," 2 to diphtheria, and not one either to measles or small-pox; in all, 102 deaths resulted from these principal zymotic diseases, against 87 and 111 in the preceding two weeks. These 102 deaths were equal to an annual rate of 4·1 per 1000, which was 0·4 below the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had increased from 28 to 53 in the previous four weeks, declined to 39 last week, of which 9 occurred in Glasgow, 8 in Edinburgh, and 6 in Paisley. The deaths referred to whooping-cough, which had been 24 and 26 in the preceding two weeks, further rose last week to 31, and included 10 in Glasgow, 8 in Dundee, and 4 in Edinburgh. The 18 fatal cases of scarlet fever showed a further increase upon recent weekly numbers; 8 occurred in Glasgow, 4 in Dundee, and 3 in Edinburgh. The 12 deaths referred to "fever," exceeded by 8 the number in the preceding week, and included 5 in Glasgow and in Dundee. Of the 2 fatal cases of diphtheria, 1 occurred in Greenock and 1 in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 69 and 73 in the preceding two weeks, were 71 last week, and exceeded by 8 the number returned in the corresponding week of last year. The causes of 67, or more than 14 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 35·5 and 29·3 per 1000 in the preceding two weeks, rose again to 37·5 in the week ending September 3rd, and exceeded the rate recorded in any week of the present year. During the first nine weeks of the current quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 21·4 in London and 18·6 in Edinburgh. The 254 deaths in Dublin last week showed an increase of 56 upon the number returned in the preceding week; they included 31 which were referred to diarrhœa, 23 to measles, 5 to "fever" (typhus, enteric, or simple), 4 to whooping-cough, 2 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 78 and 48 in the preceding two weeks, rose again last week to 65; they were equal to an annual rate of 9·6 per 1000, the rate from the same diseases being 3·4 both in London and in Edinburgh. The fatal cases of diarrhœa, which had been 27 and 13 in the previous two weeks, rose again to 23 last week. The deaths referred to measles, which had been 39 and 30 in the preceding two weeks, were 31 last week. The fatal cases of "fever" exceeded those recorded in any recent week, and the deaths referred to whooping-cough and to scarlet fever also showed an increase. The deaths of infants and of elderly persons exceeded those returned in the preceding week. Two inquest cases and 3 deaths from violence were registered; and 57, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 43, or nearly 17 per cent., of the deaths registered during the week were uncertified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: The undermentioned Surgeons-Major retire on retired pay with the honorary rank of Brigade Surgeon (dated August 31st, 1887):—James O'Reilly, M.B., and Jerome William Morgan. The undermentioned Surgeons on probation to be Surgeons (dated July 27th, 1887):—Henry Ernest Hill Smith, Wm. Perceval Gore Graham, M.B., George Forbes Alexander, M.B., Charles Stuart Spong, William Boog Leishman, M.B., Edmund McNeill Woods, M.B., James Thomson, M.B., Gerald Thos. Rawnsley, Charles William Reilly, Ernest Carrick Freeman, John Ernest Trask, William Jones Crofton, M.B., Norman Hay Forbes, Alfred Percy Blenkinsop, John Paterson, M.B., Vesey Henry William Davoren, Alfred Wright, Robert Jas. Copeland, M.B., John Girvin, Anthony John Luther, Harold Samuel Peeke, Alfred Latour Borradaile, M.B., Rich. Henry Smyth, M.B., Thomas Birt, and William Hallaran, M.B.

ADMIRALTY.—The following qualified candidates for the Naval Medical Service have been appointed to be Surgeons in Her Majesty's Fleet:—James Bradley, M.D., Geo. Hewlett, M.B., George Alexander Waters, M.D., William Gordon Stott, M.B., Charles Sharman Woodwright, Michael O'Brien, M.D., Jonathan Shand, M.B., and William Arthur Whitelegge, B.A., M.D. (dated Aug. 17th, 1887).

The following appointments have been made:—Fleet Surgeon N. Connolly, to the *Turquoise* (dated Aug. 16th, 1887); Staff Surgeon A. R. Joyce, to the *Hercules* (dated Aug. 16th, 1887); Surgeon J. A. Beattie, to the *Turquoise;* Surgeon H. F. Kiewitz, to the *Ranger;* Surgeon J. E. Penn, to the *Vernon;* Surgeon G. D. Treu-Roper, to the *Jackal;* Surgeon A. W. M'Leod, to the *Duncan;* and Surgeon W. G. K. Barnes, to the *Orontes* (all dated Aug. 16th, 1887).

ARTILLERY VOLUNTEERS.—1st Volunteer (Sussex) Brigade, Cinque Ports Division, Royal Artillery: Henry Algernon Hodson, Gent., to be Acting Surgeon (dated Aug. 27th, 1887) 1st Volunteer (Hampshire) Brigade, Southern Division, Royal Artillery: Ernest Frederic Eliot, Gent., to be Acting Surgeon (dated Sept. 3rd, 1887).—2nd Northumberland (the Percy): Acting Surgeon J. H. Davidson, M.B, resigns his appointment (dated Sept. 3rd, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the King's Own (Royal Lancaster Regiment): Acting Surgeon J. Murray, M.B., is appointed Surgeon (dated Aug. 27th, 1887).

Digitized by Google

1st Dorsetshire: Honorary Assistant Surgeon A. Emson resigns his commission (dated Aug. 27th, 1887).—2nd Volunteer Battalion, the Lincolnshire Regiment: Acting Surgeon J. P. Stewart, M.B., resigns his appointment (dated Sept. 3rd, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The Maidstone Division: The transfer of Surgeon and Honorary Surgeon-Major D. H. Monckton, which was notified in our issue of May 7th, 1887, to bear date April 1st, 1887, and not as therein stated.

Correspondence.

"Audi alteram partem."

PAIN AND ITS INTERPRETATION.

To the Editors of THE LANCET.

SIRS,—May I presume on your courtesy and space for a brief retort? I can assure Mr. Gillies I was not thinking of panegyrics in provincial "weeklies" when I said "universal experience and common sense" were against his contentions, and I am content to appeal from his to the more impartial judgment of the readers of THE LANCET as to our respective "methods." I have re-read Mr. Gillies' original article, and I adhere to my statement that he had not therein excepted cancer from his sweeping assertions as to the "eminently merciful" character of pain. It would be interesting to take the case of the travails of childbirth, and see how the rival theories supported respectively by Mr. Gillies and myself would meet that difficulty. Is pain "eminently merciful" there? Why, the theory of individual compensation—or, as Mr. Gillies finds such consolation in the *Daily News* phraseology, shall I say the "blessing in disguise theory"?—will not hold water. Evolution, on the other hand, is ready with an explanation. Man has not gained the upright posture and his cerebral development without paying heavily for these distinctions. These two factors are responsible for most, if not all, of the obstetric difficulties which woman experiences over and above the normal pains of parturition (if such there be). Evolution tells us we are but parts of a plan, and individual suffering is lost in the grandeur of the whole. If "*pain never comes where it can serve no good purpose*," what daring presumption it must be to attempt to abolish that much-disguised blessing by the use of anæsthetics! But Mr. Gillies is satisfied that all is well, every seeming exception can be disposed of, and he is not afraid that anything determined right for the individual shall be found wrong for the whole. Such optimism is refreshing, but in logic such reasoning is known as *petitio principii*, and in philosophy such assertions imply a familiarity with the intentions of Omniscience to which I dare not pretend. Glorying in teleological implications, Mr. Gillies pays me the greatest compliment he can when he says "he did not understand my rendering of the matter."

I am, Sirs, yours faithfully,
W. J. COLLINS, M.S., M.D., B.Sc. Lond.

Albert-terrace, Gloucester-gate, Aug. 28th, 1887.

To the Editors of THE LANCET.

SIRS,—I have read Mr. Gillies' "Interpretation of Pain" and Dr. Collins's criticism thereon very greedily, for "pain" is an all-engrossing subject. No one familiar with the doctrine of evolution and the rudiments of mental philosophy can fail, if he have thought the matter out for himself, to agree with Dr. Collins' critical remarks. Mr. Gillies argues for the universal beneficence of pain, but, by his acknowledged inability to follow Dr. Collins when the latter gentleman points out that the capacity for pain has very largely evolved by a survival of the fittest, Mr. Gillies foregoes what is perhaps the strongest argument in favour of his view. It is possible that pain is no necessary ingredient of mind, any more, for instance, than sight is; but whether or not (and the matter is too involved to be here discussed), there is no doubt that the capacity for pain has largely evolved by natural selection. For instance, an animal which is very painfully affected by the operation of an injurious agent is more likely to shun the same and to survive than one that is less painfully affected by it; and thus we see how by accumulation the capacity for pain has grown, and how, moreover, it has come to be a most potent weapon against evil. If by grasping with his hand a burning object a child experienced a sensation akin to that obtained by sucking a sweetmeat, a host of children would be lured on to destruction; and, indeed, we have only to look around to see how capable is pain to ward off evil. It is a common observation that delicate, hyperæsthetic people often reach a very ripe age, so carefully does their hyperæstheticism lead them to avoid injurious influences; while, on the other hand, strong and vigorous individuals are frequently prematurely cut off owing to their callousness of pain. Now, whatever evolves in an individual on the principle of natural selection must be beneficial to that individual. Therefore pain must be beneficial. But I fear we cannot say of it that it is an unmixed blessing. Viewed from a utilitarian point of view, it is decidedly imperfect, and it behoves us, as practical medical men, to know in what respect. Were pain perfect in the above sense it would have to fulfil the following conditions: It should always occur upon the first operation of an injurious agent, and should cease immediately upon its removal, or when some other useful purpose—e.g., rest—has been effected. Now, pain does not universally fulfil these conditions. It errs both by defect and by excess: for, on the one hand, it does not always occur when it can be of use, either not occurring at all or too late; and on the other hand, it arises when it can be of no use—nay, very often when it is positively harmful. It is impossible to develop these two propositions adequately in this place, for I am compelled to be very brief. Concerning the first kind of imperfection: Pain is not present in noma, nor (very often) in hydatid and several other disorders. In many diseases, though of use when it *does* come, it would have served a better purpose had it appeared earlier, during the first operation of the pathogenic agent, as in rheumatism, gout, syphilis, and the specific fevers. Finally, it may come too late, as in perforating ulcer, which may be unattended by pain till the fatal paroxysm of agony occurs. It is true that many diseases, and amongst them some of the above, are due to imprudence, the erring individual knowing well that pain will be the outcome of his conduct. But prudence depends, as Bain points out, upon the vividness of ideal pain, and if the latter is not stronger than the anticipated pleasure, so as to overcome it, it fails to deter, and the fault must be laid at the door of pain, which does not adequately persist in the memory. As regards the imperfection by excess, too many examples, alas, could be quoted; the fact can be established by asking two questions: In how many homes are good and loving people at the present moment praying for the happy *release*? How many doctors are there now struggling, might and main, against pain, not only by removing the cause, which, pushing Mr. Gillies's remarks to a practical issue, would be the only justifiable method of dealing with it, but by every means in their power, and that, too, not solely for the purpose of giving ease for a time, but very often because the pain is distinctly harmful, because, if it cannot be overcome, it may turn the scales in the favour of death? The subject of pain is an awful one, and it is one with which medical men have especially to do; but, for these very reasons, it behoves us, if we write upon the philosophy of it, to be most careful that we approach the subject from a strictly scientific point of view.

I am, Sirs, yours faithfully,
Guilford-street, W.C., Aug. 28th. HARRY CAMPBELL, M.D.

To the Editors of THE LANCET.

SIRS,—Mr. H. Cameron Gillies, in his reply to Dr. Collins's letter, makes a candid but surprising confession. He says: "As to Dr. Collins's own rendering of the matter, which I honestly confess I did not understand...." Surely there was nothing at all incomprehensible in Dr. Collins's "rendering." It would, then, appear that Mr. Gillies does not understand what every believer in the great truths of evolution must admit to be the real meaning of pain. Does, or does not, Mr. Gillies close his eyes to the fact that with the steady onward march of development and natural selection, the nervous system becomes more and more appreciative of *all* sensations? Can he deny that the greater the capacity for enjoyment becomes, the greater must also be the capacity for suffering? If Mr. Gillies deny this, it would be difficult

Digitized by Google

to convince him on any point. If, on the other hand, Mr. Gillies admit the increasing capacity for pain, why seek to find "interpretations" and "prophecies" in the realms of unsupported conjecture when pain stands out simply as an evidence of evolution? No one has ever denied the "warning cry" of pain; but to assert that a given amount of pain is, in the same measure, a prophecy of recovery, is only another way of saying "the more your nervous system is disturbed the more you are likely to survive" (in, at any rate, by far the largest proportion of cases). How is the prophecy fulfilled in the case of a man suffering the tortures of hydrophobia? The fact that some fatal lesions are unaccompanied by pain and that others are attended with intense suffering should show that pain cannot be looked upon as a constant factor, and is therefore utterly unreliable as a means of prognosis.

I am, Sirs, yours truly,

A. ST. CLAIR BUXTON, F.R.C.S.

Orchard-street, W., September 5th.

THE INOCULATION OF RABIES.

To the Editors of THE LANCET.

SIRS,—The letter in your number of Aug. 27th from Mr. Vincent Richards comes (? from India) at the right time for receiving the attention it deserves. The two questions he would submit to experiment should be answered before the practice of rabic inoculation extends. Analogy is against the view that inoculations are effective *after* infection has taken place. We vaccinate persons who have been exposed to small-pox as early as possible, in the hope that they may not then have received infection; for, happily, all do not at once suffer from the infections to which they are exposed. At one time it was thought that, as vaccination had a shorter time of incubation than small-pox—eight instead of twelve days,—if we could vaccinate within four days of the exposure to small-pox there would be time for prevention. Again, that if the vaccination could proceed to the stage of areola, it would be timely. The experience of our late epidemics of small-pox suffices to upset both theories. It is only where the person who had been exposed to small-pox had *not really been infected* that the vaccination, after the lapse of a few days, would be protective against subsequent danger. At present we have only analogy to guide us: the inoculation of rabbits has produced a form of disease with a shorter incubation than that of furious rabies; the inoculated disease may prevent danger from some future risk of being bitten by a rabid animal, and yet be powerless against the bite already received. Without the experiments suggested by Mr. Vincent Richards it would take years to set this question at rest.

I am, Sirs, yours faithfully,

September, 1887. WILLIAM SQUIRE, M.D.

GRATUITOUS ADVICE AT LONDON HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I have just had an illustration (which I think is worth recording) of the demoralising influence of gratuitous advice at London hospitals upon the upper or well-to-do classes. A lady drove up to my house with her maid, who, she informed me, was suffering from strumous abscess, but was able to attend to her duties. She had got an order for her admission into the Harrogate Bath Hospital (of which I am one of the physicians), but did not wish her to go in, as she was so useful to her. Could she have advice, waters, baths, &c., as an out-patient? I told her she could not. She then said, "She had heard how very kind I was to the poor, and that I would probably tell her what treatment the girl required, or the name of a medical man who gave gratuitous advice." I said that there were none who gave gratuitous advice under such circumstances. She then asked me what treatment I would advise, and, after receiving it, left me with profuse thanks for my kindness. I need scarcely add she did not offer to pay the fee I should have charged her, but told me how much interested her own medical man was in the case, which I have no doubt had manifested itself in the same way as I was compelled to do—viz., *gratuitously*. The case had been an out-patient in London. Comment is needless.

I am, Sirs, your obedient servant,

Harrogate, Aug. 29th. THOS. BRITTON, M.D.

VEXATIOUS ACTIONS: GIBSON AND WIFE *v.* JEFERIES AND HILLS.

To the Editors of THE LANCET.

SIRS,—May I ask you for the assistance you always so readily give to make known the grievances of our profession?

The brief account of the above case in your edition of Aug. 20th could not convey an idea of its importance to general practitioners, as well as all in the practice of midwifery. In the end of last year, owing to severe illness, I was unable to attend the plaintiff. Mr. Hills, a friend and neighbouring practitioner, at great personal inconvenience and from pure friendship and sympathy, did so for me. As was proved at the late trial, he performed his part conscientiously and with evidence (as was testified by so high an authority as Dr. Graily Hewitt) of all the necessary skill. Now what does this case show? That we are all liable at any moment, *without any grounds*, to have actions instituted against us when in the proper discharge of our duties, our professional reputation damaged, and often put to enormous expense defending an action that ought never to have been brought. Besides the injury and injustice to us, may there not be also serious consequences to our fellow-creatures if we are allowed to be so hampered in the performance of our duties? Our vocation is to endeavour to save life, and it is possible to reward our efforts, as this case and many others of late show, by an action at law with its attendant depressing anxieties and loss. I read a few days since in a daily paper of a sailor who risked his life in rescuing a drowning man; on swimming ashore with him, the latter turned on his rescuer and beat him severely. I see but little difference in his case and ours, with the exception that the sailor will perhaps more rapidly recover from the consequences. I am, Sirs, yours faithfully,

Battersea Park, Aug. 30th, 1887. W. C. JEFFRIES.

THE THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me once more a space in your columns to answer many correspondents' inquiries? The following will cover questions which have been put to me. There is no occasion for those *at present* desiring membership to secure a proposer and seconder. All who desire to join the society can do so, subject to the rule previously printed in your journal, by simply sending in their names to me or to any member of the Council. After the first meeting the admission will only be by ballot. The subscription, 10*s.* 6*d.* per annum, does not include the price of the quarterly journal, this not being yet fixed, and is not payable until after the inaugural meeting. The time and place of meeting will be duly advertised in the medical papers, and, in addition, notice will be sent by post to each member. I shall be glad to receive fresh names, as we wish to meet our President, Dr. Sydney Ringer, F.R.S., with a full congress. May I remind your readers that the subscription will be raised after the original members' list is full. Thanking you warmly for the valuable aid you have afforded the Society by granting the use of your journal for constant communications,

I remain, Sirs, yours faithfully,

64, Longridge-road, S.W. A. GEORGE BATEMAN, Hon. Sec.

THE MEDICINE STAMP TAX.

(*From a Correspondent.*)

SPASMODICALLY the officers of the Medicine Stamp Department of Somerset House make raids on chemists for selling drugs and medicines which are neither nostrums, patent, secret, nor proprietary. About two years ago they made a special crusade against all foreign medicines. This, however, created such an outcry that the Chancellor of the Exchequer, being repeatedly questioned in the House, investigated the matter, and not only annulled that portion of the medicine stamp tax which applied to foreign medicines, but further promised to bring forward at an early day, either in the then present session or the following

Digitized by Google

one, legislation for the complete revision, reformation, or repeal of the medicine stamp tax. However, the change of Government thwarted this proposed reform, and with the exception of the annulment of that portion of the Act relating to foreign medicines, no change whatever has been made. Of late the Medicine Stamp Department of Somerset House has shown excessive zeal in prosecuting chemists for selling simple pharmaceutical medicines which have not the slightest resemblance to patent medicines—e.g.: simple quinine, made up into pills by means of sugar, gum arabic, glycerine, or other excipient; quinine pure and simple, enclosed in a capsule of gelatine or covered with sugar; rhubarb, made into a fluid extract or tincture by extracting its properties with alcohols; menthol, dissolved in spirit to form a solution; powdered rhubarb and soda triturated together are under certain conditions held liable. The Board of Inland Revenue rule that each of the before-mentioned, or the mixture or combination of any two or more drugs, or the addition to a drug of any other substance (although it be but a vehicle or adjuvant), are thereby removed from the category of "medicinal drugs—entire" (or crude drugs), and become nostrums, liable to the stamp tax, in each and every case where the medical properties are stated upon the label, or set forth in advertisements to the medical profession and chemists in medical and pharmaceutical journals. All compounds and mixtures of the Pharmacopœia come under this ban according to this arbitrary ruling, and the chemist vending is liable to a heavy fine if he states the medical properties upon the label, or in any advertisements to the medical profession or trade. The chemist may not dispense paregoric, tincture of arnica, or even syrup of squills, without placing upon them a Government stamp if he states upon the label the uses of these medicines. In the case of purely family remedies, and of medicine chests for travellers, it is often of great importance that full particulars of the diseases in which they are beneficial or useful should be set forth.

It should be noted that drugs in their crude state are not liable to the stamp tax. Peruvian bark or Jesuits' powder may be advertised by nostrum vendors to cure all the ills that flesh is heir to without requiring a stamp upon it, but if quinine, its representative active principle, pure and simple, be vended with any adjuvant or other vehicle for masking its intensely bitter taste, it is, under the same conditions, liable to the enormous medicine stamp tax. One of the anomalies of the Somerset House authorities' decisions is that certain preparations can be recommended as "cure alls," though uttered in the form of patent medicines, without being required to pay the stamp tax. The natural effect of the rulings of the Somerset House authorities in respect to the discrimination between crude drugs and improved forms for administering the more eligible preparations of such drugs, is to discourage the chemist in developing the manufacture of legitimate chemical and pharmaceutical preparations. It is quite true that by a very fine technical interpretation of some of the clauses of this ancient and obnoxious Act (which has done so much to increase the sale of poisons under the protection of the stamp), it is within the power of the Board to compel chemists to stamp legitimate Pharmacopœial medicines, or suffer heavy penalties.

This tax bears with special severity upon the poor, who are by their misfortune proportionately the greatest consumers of such medicines as come under the Act. It has been well said that "the poor man, when he falls ill, besides the suspension of his daily wages and the greater necessity for nourishing food, is called upon, when he is least able to spare anything, to pay a high price for his medicine, although that medicine is a necessity of life, and without it he may remain sick, unable to work, and a burden to his family"; and "the price of medicine is of small amount to the rich and well-to-do, but to the vast masses of the labouring classes the fictitious value put on medicine by the Stamp Act is of tragical importance." This Act, be it remembered, was instituted at the time of a great national emergency as a means of raising money to carry on the war against Napoleon, and all other similar Acts of extraordinary taxation then instituted have been repealed. Great Britain stands alone of all the nations of the earth in imposing an enormous stamp tax upon medicines. The United States, with all her extravagant ideas of protection and taxation, during her great national crisis of the civil war, imposed a stamp tax of 4 per cent. on secret medicines only, which they repealed entirely very soon after the war was ended. In this country we have since 1812 exacted the heavy tax of 12½ per cent. on medicines selling for 1s. and upwards, while medicines selling for 6d. such as are consumed most by the very poor, have to pay the enormous sum of 25 per cent., and more than half of the entire medicine tax is collected on these smallest stamps.

The Times (August 7th, 1884), referring to this Medicine Stamp Act, says: "Common sense, common prudence, coupled with commercial interests, alike clamour for its repeal"; and on August 13th, 1884, says: "If a medicine be good, it is surely unjust to raise its price by a tax." The British Medical Association passed strong resolutions praying for the absolute repeal of the medicine stamp tax, declaring that "it is unjust to impose a tax upon medicines."

But it is not alone the burden that this iniquitous Act imposes upon those least able to bear it that has to be considered; it affords a sheltering guise beneath which dangerous poisons, which ought only to be administered under a physician's prescription or direction, can be placed freely within reach of the public. If for want of time the Government cannot take immediate steps to repeal the entire Act, they should, without a moment's delay, annul those clauses which apply to any and all medicines which do not come under the head of patent or secret compounds. It is certainly within the power of the Chancellor of the Exchequer to do this, as there are abundant precedents—one, indeed, in connexion with this Act — namely, the annulment of the clause relating to foreign medicine, by Mr. Childers when Chancellor of the Exchequer in Mr. Gladstone's Government.

LIVERPOOL.

(From our own Correspondent.)

THE ENLARGEMENT OF THE BOOTLE HOSPITAL.

BOOTLE, which forty years ago was a pleasant little village within easy distance of Liverpool, has grown to be an incorporated town, containing about 30,000 inhabitants. What was formerly the Bootle Dispensary, instituted in 1846, expanded first into a cottage hospital, and next, in 1872, into a hospital containing 38 beds. For some time past these latter have been found quite insufficient to supply the demand for patients whose condition rendered treatment within the hospital absolutely necessary. On Aug. 27th an addition to the hospital was opened by Mr. T. H. Ismay in the presence of the Mayor (Alderman Wm. Jones) and many of the local clergy, ministers, and leading townsmen. This new portion contains wards named the "Derby," the "Artisans," and the "Danson" wards, with recreation room, operating rooms, out-patients' department, &c. Accommodation for infectious cases has been provided in separate wards so as to admit of perfect isolation. Towards the cost the sum of £1564 had been raised by the Jubilee Committee, it having been previously decided that this should be Bootle's tribute of loyalty to the Queen. The total cost is £11,800, nearly all of which has been provided, a Mr. Rowlandson furnishing one ward, and the *employés* of the White Star Company another.

THE SATURDAY HALF HOLIDAY AND CRIMES OF VIOLENCE.

In addition to the many accidents at the docks and elsewhere which furnished patients for the Bootle hospital, the town has a most unenviable notoriety for crimes of brutal violence, frequently resulting in death, and generally occurring on the afternoon or evening of Saturday. So established was this as a fact, that it led to the pleasantry of substituting "Brutal" for "Bootle." It is believed that a newly organised police force will effect a change for the better; and it is also hoped that working men will be induced to employ their half holidays in a more rational manner than in those drunken debauches in the public-house which both in Bootle and Liverpool are the precursors to acts of violence. It is not many years ago since the late Baron Martin greatly offended local susceptibilities by describing one of these cases brought before him as "a regular Liverpool case." And yet it was perfectly true.

THE MIXTURE OF DRUGS.

At the Police Court on Sept. 2nd a chemist was fined £5 and costs in the first of four charges of mixing methylated spirit with pure spirits of wine; fines of £1 and costs being

Digitized by Google

inflicted in the remaining three cases. The prosecution was taken up by the Inland Revenue, an officer of which called at different establishments of the defendant, and purchased paregoric, tincture of Cayenne, and sweet spirits of nitre, all of which were found to contain a quantity of methylated spirit. The defence was that it had been done by the assistants to conceal the fact that they had been drinking the spirits of wine.

"CHEWING GUM."

A local confectioner has been fined five shillings and costs, amounting in all to twenty shillings, for selling as "chewing gum" a compound which, according to Dr. Campbell Brown's analysis, contained 38 per cent. of solid paraffin, the remainder being composed of sugar and colouring matter.

Liverpool.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SEA TRIP FOR THE POOR.

MR. T. S. ALDER, a chemist of this city, last week organised a most successful seaside excursion for the poor children of this city, as well as for such of the aged poor as were able to join the excursion. About 5000 children and 1000 adults were conveyed in special steamers from Newcastle Quay to Tynemouth, where they were treated to games and various amusements on the sands, finishing up with tea &c., and all were safely taken to their homes, not a single accident occurring to mar the day's enjoyment. But it is well to allude to a point which may be remembered should the trip be repeated another year; and it is that children in a state of activity at the seaside have very brisk digestion and soon begin to suffer acutely from hunger; in this case they were kept far too long without food, notwithstanding the abundant supply provided. All the other arrangements were perfect, including ambulance attendance under Dr. Lightfoot, &c. But with active children frequent feeding is a *sine qud non*.

POISONING BY ACONITE.

A sad case of accidental poisoning by aconite occurred last week at Fence Houses, a village in the county of Durham. A man named Hughes asked his wife early in the morning to hand him a liniment, which he was using for his back; she did so, and put the bottle back in a cupboard. Soon afterwards he wanted some cough mixture, and took out the liniment bottle in mistake, drinking a teaspoonful in half a wineglassful of cold water. The mistake was immediately found out by the man and his wife, and Dr. McGill was called in, under whose treatment he revived for a while, but soon afterwards died from the effects of the poison.

JARROW.

The Memorial Hospital erected about ten years ago by Sir C. M. Palmer to the memory of his wife has been so useful that an extension is necessary, which will comprise a boy's ward, a girl's ward, lying-in ward, medical department, with extension of the dispensary and other necessary offices.

TYPHUS IN NEWCASTLE.

Our medical officer of health has presented a special report on the recent outbreak of fever in Newcastle. Mr. H. E. Armstrong's report presents many points of interest forcibly put as to the Corporation having powers to remove all cases to hospital where isolation could not be carried out for want of requisite means. Mr. Armstrong points out that another lesson from the outbreak is the importance of medical students being taught the different varieties of fever and other infectious diseases as part of their curriculum.

Newcastle-on-Tyne, Sept. 5th.

THE SANITARY INSTITUTE OF GREAT BRITAIN.—The Institute has issued its preliminary programme of the tenth Congress, to be held at Bolton on the 20th inst. and four following days. The opening address will be delivered by Lord Basing, F.R.S. On Wednesday an address will be given by Dr. Russell Reynolds, F.R.S., in the Section of Sanitary Science and Preventive Medicine. On the following day Professor Hayter Lewis, F.S.A., will discourse on a subject connected with sanitary engineering and architecture. On Friday Dr. Dupré, F.R.S., will deliver an address in the Section of Chemistry, Meteorology, and Geology. On Saturday addresses will be delivered to the working classes by various gentlemen on subjects of popular interest from a public health point of view.

DUBLIN.

(From our own Correspondent.)

LOCAL GOVERNMENT BOARD FOR IRELAND.

IN the last annual report attention was drawn to the fact that there was a decrease in the average daily number of persons relieved in the workhouses in the year ending Jan. 1886, as compared with the number relieved in the preceding year. The returns for the year under consideration show a further decline in the average daily number of persons relieved in the workhouses. On the other hand, there has been an increase of 19,276 persons in the average daily number who obtained out-door relief, but this increase was mainly due to the operation of the Poor Relief Act of last year. During the twelve months ending January 15th last, the total number of deaths in the workhouses amounted to 10,694, being a decrease of 281 as compared with the previous return. Deaths by fever were 346, as against 371; by lung disease, 1848, as against 1997; and there was only one death from small-pox, being one less than in the previous year. As regards the number of cases in which medical relief was afforded under the Medical Charities Act, it appears that there was a decrease of 18,085, including those prescribed for at dispensaries, and attended at their own homes, as compared with the preceding year. During the year ended September 30th, 1886, 94,361 persons were vaccinated, showing a considerable decline, amounting to 7451 as compared with the previous year. The total expenditure of poor-rates for poor relief, medical relief, burial grounds, sanitary measures, superannuation, &c. was in 1886, £1,360,597, or an increase of £102,132.

HYDROPHOBIA.

Lord Donerailе's death from hydrophobia makes, it is stated, the ninety-sixth death of persons who have undergone M. Pasteur's method of treatment. A large number of those who have been bitten by rabid animals recover no matter what treatment is used; and, therefore, the apparent cures by a certain method of treatment require to be largely discounted. On the other hand, when nearly 100 persons have succumbed from hydrophobia, although M. Pasteur's directions have been carefully caried out, it shows undoubtedly that up to the present a specific for the cure of this dread malady has not yet been discovered.

THE PREVALENCE OF OPHTHALMIA IN THE CORK WORKHOUSE.

The Cork guardians last week received from the Local Government Board the report of their inspector, Dr. O'Farrell, on the prevalence of ophthalmia in the workhouse. He states that the schoolrooms and dormitories are cheerful, clean, orderly, and well ventilated. The ventilation of the boys' hospital, as pointed out by Dr. Sandford, needs improvement, and the sewerage of the entire school buildings require attention. The playgrounds being covered with limestone gravel the children are enveloped in clouds of dust during dry weather, which must have a most irritating effect on their eyes, tender and predisposed as so many of them are to ophthalmia. As regards the important question of treatment, the report considers (1) the means likely to check the present outbreak, and (2) those general hygienic measures which favour the origin and propagation of ophthalmia and other diseases among them. The essence of acute ophthalmia being contagion, he recommends that all children who have discharge or other active symptoms should be isolated as far as possible; while attention should be paid to the lavatory and bathing arrangements. He suggests increased medical inspection and supervision, and recommends that the guardians should appoint a house-surgeon or assistant house-surgeon, preferably one with a special knowledge of eye diseases, who would undertake the supervision and treatment of all the children; that he should examine all fresh admissions into the schools, and that he should treat the severe eye cases in hospital under the direction of the visiting medical staff. Dr. O'Farrell also recommends increased attention to physical training; and that all the children should be encouraged to use gymnastic exercises. The schools and dormitories should be heated during winter, and there should be increased accommodation for the younger children, so that each should have a separate bed, also increased attention to their cleanliness and physical development. These

Digitized by Google

are the main points dealt with in a very able report, and a special meeting of the guardians has been called to consider it.

THE COACHFORD POISONING CASE.

Dr. P. Cross, retired surgeon-major, A.M.D., who was arrested on suspicion of having poisoned his wife, will be tried at the next sessions.

Last week Madame Marie Roze visited Jervis-street, and sang a number of songs for the amusement of the inmates.

Dublin, Sept. 6th.

BELFAST.

(From our own Correspondent.)

THE ROYAL HOSPITAL.

FROM the report presented at the last quarterly meeting (held on Aug. 22nd), we learn that during the past three months 469 intern patients, and 2819 extern patients were treated. Great regret was expressed owing to the death of Prof. Gordon and Dr. J. Moore, who for a long series of years were surgeons to the hospital. In reference to the important subject of finance, we find that a total of £3269 7*s.* 1*d.* has been received for the present year. The total expenditure up to the end of July, including the balance due at the end of last financial year, has been £3948 10*s.* 1*d.* Of this amount the sum of £1100 2*s.* 8*d.* is still unpaid. The ordinary income of the hospital still falls far short of the ordinary expenditure, but fortunately during the present year there have been some special sources of income which enable the Board to meet the claims upon them without strain or inconvenience. During the past eleven months the sum of £4000 has been invested to the credit of the hospital. In accordance with a rule of the hospital, all the attending medical officers are elected for periods of four years, at the end of which they retire, but are eligible for re-election. The following members of the staff, whose term of office had expired, were re-elected at this meeting. Physician: Dr. Ross. Physician for Diseases of Women: Dr. John W. Byers. Surgeon: Dr. Walton Browne. Ophthalmic Surgeon: Dr. Joseph Nelson. Assistant Physician: Dr. J. A. Lindsay.

ULSTER MEDICAL SOCIETY.

At the annual meeting of this Society held on Aug. 24th, the report, giving full details of last year's work, and the treasurer's statement, which showed that there is a substantial balance in hand, were submitted. Dr. Robert Esler was elected President, and Dr. John Macaw Secretary for the ensuing session.

THE MORGUE.

A short time ago public attention was drawn to the situation of this building by the circumstance that an owner of property in the neighbourhood made an application at the police court. He stated that owing to the presence of the Morgue his property is seriously deteriorating, that his tenants are leaving, and that disease may at any time break out among the children who are constantly running about in its vicinity. The matter was brought before the Public Health Committee of the Town Council. At this meeting it was shown that bodies of persons who have died of infectious disease are not taken to the Morgue, and that only those who have been drowned or have in some other way come to a sudden death are left in this place. The subject was ultimately referred to Dr. Samuel Browne, consulting sanitary officer of Belfast, and it is hoped that arrangements may be made by which this most unhandsome building may be removed from its present situation in the centre of Belfast.

HOSPITAL SATURDAY.

The recent collection throughout Belfast for the Royal Hospital realised the sum of £226 10*s.* 6*d.* Although the day was rather unfavourable, it must be admitted that, considering the population of the town (220,000), this is anything but satisfactory, and the more to be regretted as it shows a falling off from last year.

Belfast, Sept. 3rd.

A Sister of the Red Cross at Odessa has been bitten on the hand by a man suffering from hydrophobia whom she was nursing. She has been treated as if she had been bitten by a rabid dog.

PARIS.

(From our own Correspondent.)

M. LUYS AND HYPNOTISM.

THE Academy of Medicine of Paris is not only a learned society. It serves also as a consulting body to the Government in matters of public health, and hence the utterances which receive its sanction may be taken to represent the official science of the day. Hitherto its members have been sober—at any rate, in the precincts of the Academy—in their expression of opinion concerning hypnotism; and if communications have been made from time to time on this subject, they have mostly been characterised by mere triviality, the more irrational statements in the so-called "psychical" science having been reserved for the other societies. M. Luys, however, is ambitious of official recognition for the vagaries of hypnotism; and he has had the happy idea of entertaining the Academy with his researches about the "Solicitation expérimentale des phénomènes émotifs chez les sujets en état d'hypnotisme." It is regrettable that the "facts" stated at the last meeting should have been brought forward by one who has hitherto enjoyed the reputation of a *savant* on cerebral physiology, and whose work on the brain is a standard text-book; but M. Luys will have done a service in forcing the Academy to an expression of opinion concerning the practices carried on in many of the Paris hospitals, where hypnotism, daily misapplied under a therapeutic pretext, has nearly constantly one only effect—that of destroying the mental and moral equilibrium of those previously sound in this respect, and of inducting many patients into the gravest degradation of hysteria. M. Luys' communication relates to the action of certain medicines upon hypnotised subjects by radiation, from the inside of hermetically sealed glass tubes. This interesting discovery, which dates, at any rate, from Hahnemann, was rediscovered by MM. Bourru and Burot, and related by them at the Congress of Grenoble, and they have since written a book on the subject. M. Luys has repeated and extended their experiments with eighty-six different substances, and finds that the effects produced upon the hypnotised organism by the action of the stimulating agents are of two orders. In one the subject is silent, and reacts as an automaton; morphine, strychnine, valerian, and sparteine produce phenomena of the kind. In the other the subject enters into the phase of lucid somnambulism, hears and enters into communication with the outside world. This is effected by Indian hemp, coffee, alcohol, and various odorous substances. In the first series of experiments the subjects are placed in a state of lethargy. The sealed tube containing the medicine is put at the nape of the neck, and in a short time the face expresses a state of feeling—generally that of displeasure. In those who enjoy a dual personality (*sujets dedoublés*) the same substance will provoke an expression of suffering or malaise when applied to the right side of the brain, and a state of joy and expansion when placed on the left. Essence of thyme causes the submaxillary and thyroid regions to swell, the face to become turgescent, and the eyes to protrude. It must be noted that all this is recorded photographically. Morphia placed on the left side of the nape of the neck gives rise immediately to a feeling of terror. If the application is continued, the subject, actuated by the "instinct of protection," expresses the greatest anger. Upon changing sides and placing the tube behind the right ear, this subsides, and the face becomes calm and placid. Strychnia produces convulsions when applied on the left side; on the right, a state of gaiety and "jubilation." To quote a last example: Valerian gives rise to emotions having a character of great sadness. "The subject," says M. Luys, "is under the influence of an irresistible impulse to scrape the earth. He kneels down to do so, and the idea comes to him that he is in a cemetery. He performs the exhumation of a beloved friend, placing aside the soil with his hands and piously gathering together the remains. He makes a little mound upon which he places a cross, and goes through the funereal ceremony with groans, genuflexions, crossings, and kissings of the earth!" Not only is the preceding statement profoundly ridiculous, coming from a physician versed in mental science, but it is also opposed to what was obtained with the same agent by MM. Bourru

Digitized by Google

and Burot. Valerian was found by these observers to cause "violent excitement," and to give rise to the same emotions as in a cat. The subject runs about sniffing, scratches a hole, and places his face in it. If these were isolated experiments, having been only preceded by those already mentioned—as the perpetual secretary of the Academy, in expressing his astonishment at M. Luys' communication, seemed to believe,—it would scarcely be worth while to discuss their explanation; but according to M. de Rochas, who has published a recent work on "Non-defined Forces," similar results have been obtained in the wards of M. Brouardel, the present dean of the Faculty, of M. Charcot, and of M. Dumontpallier. In the wards of M. Dumontpallier, "opium (applied in tubes), has induced sleep in a hystero-epileptic. In M. Charcot's service a woman submitted to alcohol presented an irresistible sleepiness, staggering, heaviness of the head, moderate and agreeable intoxication, and vomiting—symptoms which were arrested by ammonia. In a patient (!) in the service of M. Brouardel the action of alcohol was chiefly exerted on the legs. Valerian caused heaviness of the head, somnolency, and a kind of drunkenness." There can be no doubt that these experiments have been performed with the results published; and, if the experimenters think that the application of their tubes and the symptoms which follow have a relation of cause and effect, they are, of course, entitled to that belief. But in my opinion the experiments are carried on in the very worst possible conditions for a scientific test, and in many cases the observers seem not only to ignore the psychology of hysteria, but also to be unacquainted with the most elementary principles of hypnotism. I have seen the operator guilelessly whisper to a visitor that such and such an effect would be produced, apparently unaware of the fact that in the hypnotic condition there is a state of hyperacousia which makes the faintest sound audible. When the subject does not actually hear what is the name of the medicine under experiment, she is almost sure to have to go through her performance in a certain order. The experimenter generally shows the phenomena *crescendo*, from the less to the more astounding, and should there be any change in this respect to the trained subject the expression of the face and the inflexion of the voice are very sufficient guides. There is also such a thing as auto-suggestion, and from what I have seen, it is very often the would-be suggester who comes away from the séance with a delusion.

Paris, Sept. 7th.

Obituary.

THOMAS CUMING, M.D., F.K.Q.C.P.I.

WE have to record the death of one of the oldest medical practitioners in Ulster—Dr. Thomas Cuming, who died on Sept. 4th, at his residence, Armagh, in his ninetieth year. Dr. Cuming studied at Edinburgh and Dublin, and was a graduate of both Universities, and he was also elected a Fellow of the King and Queen's College of Physicians, Ireland. He was for a time physician to the Wellesley Fever Hospital, Dublin, and assistant physician to the Institution for Diseases of Children, Pitt-street, Dublin. He was also at one time lecturer on Practice of Medicine at the Richmond School of Medicine, and on Diseases of Children at the Pitt-street Institution, Dublin. When a very young man Dr. Cuming settled in Armagh, where he soon found himself fully occupied with a serious outbreak of fever; and so much was he personally respected, and his skill as a physician admitted, that he rapidly came to the front as the leading medical man in Armagh and the surrounding district. For many years he was consulting physician to the Armagh Lunatic Asylum, of which he was a trustee; and when a younger man he was an active member of the Armagh Natural History and Philosophical Society. It is said that never but once for sixty years was he absent from the annual meeting of the Armagh auxiliary to the Hibernian Bible Society. He was physician to the late Lord Primate of Ireland, and it was during his visits to the Palace in the winter that he caught a cold, and for a time it seemed doubtful as to whether the doctor or his patient would succumb first. It was a great grief to him not to be with his friend the Lord Primate to the end of his last illness. Dr. Cuming was a man highly beloved and respected both as a friend and as a physician, and his death removes one of the links connecting the present with the past generation.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates to practise as Licentiates of the Society on Aug. 15th:—

Atkinson, Guy C. Barlow, Danby Parsonage. Grosmont.
Bays, James Thomas, Queen-street, Peterborough.
Blake, Edwin H., Claremont, Cleveland-rd., Wanstead, Essex.
Cotton, John, Holly Mount, St. Anns, St. Helens, Lancashire.
Heelas W. Wheeler, The Holt, Wokingham, Berks.

The following gentlemen passed the examination in Surgery held on July 27th and 28th, and Aug. 10th, 11th, 24th, and 25th—

Bays, James Thomas, St. Mary's Hospital.
Beaumont, William Henry, the London Hospital.
Buist, James Joseph, St. Bartholomew's Hospital.
Clarke, Edward Alfred, Owens College, Manchester.
Ellis, William, St. George's Hospital.
Fletcher, Frederick James, Queen's College, Birmingham.
Garvey, Henry Patrick, Dublin.
Gunning, Montague Shirley Wyatt, University College.
Hudson, James Wasdale, Middlesex Hospital.
Jenkinson, Joseph Arthur, Owens College, Manchester.
Parsons, George Gooden, London Hospital.
Williams, William Wilfred, Guy's Hospital.

At the recent examination for the prizes in Materia Medica and Pharmaceutical Chemistry, given annually by the Society, the successful candidates were:—

First. William McAdam Eccles, student of St. Bartholomew's Hospital. The Gold Medal.
Second. Alfred Banks, student of St. Thomas's Hospital. The Silver Medal and Books.

VACCINATION GRANT.—Mr. R. L. Shone, medical officer to the Mortlake district, has received the Government grant for successful vaccination in his district (third time).

AT a meeting of the Merthyr Tydvil Local Board on the 7th inst., it was reported that an outbreak of typhus had occurred at Dowlais.

DEATH WHILE UNDER THE INFLUENCE OF CHLOROFORM. The death, in the Gloucester Infirmary, of a patient to whom chloroform had been administered preparatory to an operation rendered necessary by an injury to the hand, is reported.

PROFESSOR GUSTAF BRAUN has, it is reported, sent a telegram from Vienna to the Queen of Denmark respecting the Duchess of Cumberland, stating that "the physical and mental condition of Her Royal Highness is very satisfactory."

ON the 6th inst. a public inquiry was held at Chichester, before Major Hector Tulloch, R.E., a Local Government Board inspector, with reference to the application of the Town Council for powers to borrow a sum not exceeding £2250 for the purpose of building an infectious diseases hospital.

HOSPITAL SATURDAY FUND.—On the 3rd inst. the subscriptions of the various industrial establishments of London on behalf of this fund became due. It is of course too early to speak with any degree of certainty as to the result of the workshop collection, but it is confidently believed that it will reach at least £7000.

SCARLET FEVER IN DUNDEE.—During last month there was an alarming increase of infectious disease in Dundee. Notwithstanding the exertions of the sanitary authorities, scarlet fever is now very prevalent in the town. The disease is not confined to any particular district, and last month ended with a total of 294 more cases than on the 31st of July.

TEMPERANCE SUNDAY.—At a gathering of representatives from various religious bodies, held at the Memorial Hall, Farringdon-street, on the 6th inst., it was resolved:—"That this conference of representatives of the principal Nonconformist temperance organisations unanimously recommends that the last Sunday in November in each year should be observed as Temperance Sunday." The conference also unanimously recommended that a united demonstration be held during the week following the sermons in November.

Digitized by Google

NEW COTTAGE HOSPITAL AT SYDNEY.—The ceremony of laying the foundation stone of the new buildings for the Cottage Hospital at North Shore, Sydney, was performed by Sir Henry Parkes on the afternoon of June 4th. The buildings will contain three wards for men, women, and children, will accommodate about forty patients, and have all the necessary offices required for the proper treatment of the sick.

ULSTER MEDICAL SOCIETY.—The annual meeting of this Society for the election of office-bearers was held recently in the Museum, Belfast. The retiring president, Dr. Whitla, was strongly urged to accept re-election in recognition of his valuable services during the past session, but declined the proffered honour owing to press of engagements. On the motion of Dr. Whitla, seconded by Dr. Burden, Dr. Esler was then unanimously elected president for the ensuing year. Several members bore testimony to Dr. Esler's untiring labours as treasurer and in other subordinate offices, which contributed in so large a measure to the numerical strength and financial prosperity of the Society. The other offices were filled as follows:—Vice-presidents, Dr. Dempsey and Dr. O'Neill; treasurer, Dr. Stanley B. Coates; secretary, Dr. M'Caw; librarian, Dr. Strafford Smith; pathological secretary, Professor Sinclair; Council—Professor Dill, Dr. Kevin, Dr. Calwell, Dr. O'Connor, Dr. Bigger, and Dr. Burden.

THE SALARIES OF MEDICAL OFFICERS OF HEALTH.—At a meeting of the Totnes Union Rural Sanitary Authority, held on the 3rd inst., a letter was read from the Bodmin Rural Sanitary Authority on the subject of the remuneration of a medical officer of health, the Local Government Board having refused to sanction the appointment of their officer on the ground of the inadequacy of the salary, thereby depriving them of a moiety of the salary allowed by the Parliamentary grant. The Bodmin Authority considered the action of the Board arbitrary and unreasonable, and in view of the possibility of other unions having experienced the same difficulty, it had been suggested that united action on the part of those who were similarly affected might be the means of securing a fair and proper consideration of the whole matter. Another letter on the same subject was read from the Sanitary Authority at Okehampton. After some discussion it was decided that the clerk should ascertain the salaries paid by other authorities, and further consideration of the question was then adjourned.

THE BURMESE CAMPAIGN.—The *London Gazette* of the 2nd inst. contains dispatches received by the Secretary of State for War from the Secretary of State for India in Council relative to the Burmese campaign. The Viceroy of India mentions the name of Deputy Surgeon-General J. McN. Donnelly. The Commander-in-Chief in India mentions the services of Surgeon-Major W. Taylor, Medical Staff, and Deputy Surgeon-General G. Farrell, C.B. Brigadier-General Anderson mentions the following officers:—Surgeon-Major T. W. Patterson, Medical Staff, Senior Medical Officer, 4th Brigade, and Surgeon-Major F. W. Wright, M.B., Indian Medical Service. The following officers have been brought to notice by Brigadier-General Stewart for good service:—Surgeon J. P. Barry, M.B., Indian Medical Service, and Surgeon W. A. Sykes, Indian Medical Service. Brigadier-General Low, C.B., has named the following officers:—Surgeon-Major J. F. Supple, Senior Medical Officer, 6th Brigade, and Surgeon A. P. Adams, Indian Medical Service. Brigadier-General Cox has brought the following officer to notice:—Surgeon-Major J. S. Wilkins, Indian Medical Service. The Principal Medical Officer has recommended the following medical officers for special zeal and ability:—Surgeon-Major R. de la Cour Corbett, M.D., Medical Staff; Surgeon R. V. Ash, M.B., Medical Staff; Brigade-Surgeon W. H. Roberts, M.D., Madras Medical Service; Surgeon-Major T. W. Patterson, Medical Staff; Surgeon D. Elcum, Madras Medical Service; Surgeon H. K. Fuller, M.B., Madras Medical Service; Surgeon-Major E. Fawcett, Madras Medical Service; Surgeon-Major J. S. Wilkins, Bombay Medical Service; Surgeon-Major W. Venour, Medical Staff; Surgeon-Major F. W. Wright, M.B., Bengal Medical Service; Surgeon-Major C. F. M'Vittie, Madras Medical Service; Surgeon M. O'C. Drury, Medical Staff; Surgeon W. A. Sykes, Bengal Medical Service; Surgeon-Major J. F. Supple, Medical Staff; Surgeon-Major C. F. Ogilvie, M.D., Bombay Medical Service; Surgeon-Major J. T. B. Bookey, Bengal Medical Service; Surgeon-Major R. D. Murray, M.D., Bengal Medical Service; Surgeon J. Macgregor, M.D., Bombay Medical Service; Surgeon W. A. Morris, Medical Staff; Surgeon P. F. O'Connor, Bengal Medical Service; Surgeon R. E. S. Davis, M.B., Madras Medical Service; Surgeon A. P. Adams, Madras Medical Service, of whom General White selects the following for special mention:—Surgeon-Major R. de la Cour Corbett, M.D., Medical Staff; Surgeon-Major R. V. Ash, M.B., Medical Staff; Surgeon-Major T. W. Patterson, Medical Staff; Surgeon-Major J. S. Wilkins, Bombay Medical Service; Surgeon-Major W. Venour, Medical Staff; Surgeon-Major F. W. Wright, M.B., Bengal Medical Service; Surgeon W. A. Sykes, Bengal Medical Service; Surgeon-Major J. F. Supple, Medical Service; Surgeon A. P. Adams, Madras Medical Service. General White mentions the services of Deputy Surgeon-General G. Farrell, C.B., and Surgeon-Major H. W. A. Mackinnon. Brigadier-General W. S. A. Lockhart, C.B., C.S.I., Commanding the 3rd Brigade, submits an additional list of officers in his command who have rendered good service up to date, in which appear the names of Surgeon W. G. Birrell, M.B., Medical Staff; Surgeon A. W. F. Street, Indian Medical Service; Surgeon P. de Conceiçao, Indian Medical Service; and the late Surgeon E. W. Kelsall, Medical Staff. Colonel Stedman mentions the names of Surgeon-Major J. C. G. Carmichael, M.D., 3rd Goorkha Regiment, Surgeon A. W. F. Street, Bombay Medical Service; and Surgeon P. C. H. Gordon, Medical Staff. Major-General J. J. H. Gordon, C.B., commanding the Eastern Frontier District, March 21st, mentions the services of Surgeon F. A. Rogers, Indian Medical Service.

MEDICAL NOTES IN PARLIAMENT.

House Boats on the Thames.

IN the House of Commons, on the 1st inst., Mr. Coghill asked the President of the Local Government Board whether he was aware that since his attention was called to the matter in February last the water of the Thames had continued to be polluted by the sewage and other refuse of house boats and steam launches.—Mr. Ritchie said that since March last two bye-laws which had been made on the subject by the conservators had come into force on June 18th. Shortly after that date the conservators addressed notices to the owners of house boats, drawing special attention to the requirements of the bye-laws to prevent the pollution of the river by the discharge of sewage. He had made further communications with the conservators, asking what steps they had taken to see that their bye-laws were carried out.

Rank of Army Medical Officers.

On the 5th inst., in answer to Dr. Clark, Mr. Stanhope repeated the statement that the recent Royal Warrant by abrogating relative rank detracted in no sense whatever from the status, precedents, or privileges of medical officers. Whatever privileges they had under Clause 17 of the Royal Warrant of 1858 they have now, with this exception, that in some cases they rank higher than they then did. He was not aware that there was any difficulty in obtaining qualified candidates. The hon. member was quite mistaken in supposing that he had promised a committee, nor did he think that it would serve any useful purpose.

Fever Hospitals.

On the 6th inst., in reply to the Marquis of Carmarthen, Mr. Ritchie stated that the question whether the South-Western Hospital or that at Winchmore-hill should be opened was considered by the managers of the Metropolitan Asylums Board, who determined by a considerable majority in favour of opening the former. The Winchmore-hill Hospital was not furnished, and it would, therefore, have taken longer than the other hospital to prepare for patients. The matter, however, was one of urgency, and the committee had already found it necessary to act upon the resolution of the managers, and to open the South-Western Hospital. No evidence had been adduced to show that during the seventeen years which have elapsed since this hospital was first opened fever has spread from it to the surrounding houses, and, under all the circumstances, he had not thought it necessary to interfere with the decision of the managers on the subject.

The Medical Staff in India.

Sir W. Foster asked the Under-Secretary of State for India whether an executive officer of the medical staff in India, who officiated for less than one month as Deputy Surgeon-General, in the absence of the Deputy Surgeon-General on sick leave or furlough, received no allowances for the period, although he performed the duties in addition to his other duties; whether in such an instance the "half-staff" of the appointment reverted to the State; whether the acting officer would be held pecuniarily liable in the event of loss of stores or other mistakes; and whether officers officiating on the military (combatant) staff in a similar way would draw the "half-staff" for broken periods, and why the difference was made in the case of medical officers.—Sir J. Fergusson, in reply, said that in accordance with the undertaking given by him on June 17th, when this question was first put, a despatch on this subject was addressed to the Government of India, but no reply had yet been received.

The Burning of the Exeter Theatre.

Sir J. Puleston asked the Home Secretary whether as the Exeter Theatre had been recently built any official survey had been made before it was open.—Mr. Matthews replied that no official survey was held by the Home Office, because the Home Office has no authority in the matter. The jurisdiction lies with the justices at special sessions.—Dr. Tanner

Digitized by Google

said he wished to ask the Secretary of State for the Home Department whether, in consequence of the frequently recurring disasters and loss of life in theatres and other places of public amusement, steps would be immediately taken to appoint two or more inspectors under the department whose duty it should be to inspect all places of public amusement in Great Britain and Ireland, and who should have power at once to prevent any performance or public meeting being held in such theatres or places as should not be adequately provided with commodious exits for use in all cases of sudden emergency; and, also, whether, bearing in mind the fact that most fires originated on the stage, as was the case in the dreadful calamity last night in Exeter, the iron drop scene should in future be deemed a necessary appurtenance to every theatre.—Mr. Matthews regretted to say that it would not be possible to act on the suggestion without legislation. Outside the metropolitan area there was no power in any Government department or in any local authority to inspect theatres or to insist on structural alterations in an existing theatre. Within the metropolitan area the Metropolitan Board of Works have sufficient powers to enforce the precautions which they may deem necessary; and they have largely acted on those powers. The dreadful calamity which has occurred at Exeter shows the necessity of legislation for provincial theatres, and the Government would give their attention to the subject.

Mr. Lawson obtained leave to introduce a Bill, which was read a first time, to prevent nuisances on vacant grounds and open spaces.

Births, Marriages, and Deaths.

BIRTHS.

COLLINS.—On the 5th inst., at Jessamine Cottage, Ash-next-Sandwich, Kent, the wife of M. J. Collins, L.R.C.S.Ed., &c., ex-Surgeon, R.W.J.M.S., of a son (Reginald Michael).

FRANKS.—On the 2nd inst., at Fitzwilliam-square, Dublin, the wife of Kendal Franks, M.D., of a daughter.

ISAAC.—On the 1st inst., at Mornington-crescent, N.W., the wife of G. Washington Isaac, M.B., of a daughter.

ORR.—On the 30th ult., at Wollaston, Wellingborough, the wife of James W. Orr, of a daughter.

PARSON.—On the 6th inst., at Cumberland House, Kew, the wife of C. Jenner Parson, M.D., of a daughter.

PHILLIPS.—On the 1st inst., at Denny House, Waterbeach, near Cambridge, the wife of H. Astley Phillips, M.D., of a son.

RAHILLY.—On the 1st inst., at Merton Lodge, Clifton, the wife of Surgeon-Major Rahilly, Army Medical Staff, of a son.

ROBERTS—On the 29th ult., at Ealing, the wife of H. Prescott Roberts, M.D., prematurely, of a daughter (stillborn).

STEEL.—On the 5th inst., at Radnor Villa, Upper Chorlton-road, Manchester, the wife of Graham Steell, M.D., of a son.

WHEELER.—On the 27th ult., at Pembridge-gardens, W., the wife of John Wheeler, M.D., M.Ch., M.A.O., of a daughter.

WHYTE.—On the 30th ult., at Lovegrove-terrace, Mile-end, Portsmouth, the wife of Alexander Whyte, M.B., M.R.C.S., of a son (stillborn).

MARRIAGES.

ARCHER—LOWNE.—On the 3rd inst., at St. Michael and All Angels', North Kensington, W. G. Archer, Esq., M.B.Cantab., F.R.C.S., son of the late John Archer, Esq., F.R.C.S., of Birmingham, to Nellie, the only daughter of Benjn. Thompson Lowne, Esq., F.R.C.S.

HARVEY—MARSHALL.—On the 1st inst., at the Parish Church, Mitcham, Surrey, by the Rev. F. Legg, Vicar of Christ Church, Mitcham, assisted by the Rev. O. H. Seaton, Thomas Pashley, eldest son of the late G. T. Harvey, of Baron Grove, Mitcham, to Helen May, second daughter of Edward Marshall, Surgeon, of Church House, Mitcham, Surrey.

HOPE—BRIGGS.—On the 31st ult., at St. John's, Angell Town, Brixton, by the Rev. C. J. Rashleigh Cooke, M.A., Vicar, George Hope, L.R.C.P., M.R.C.S., L.S.A.Lond., only son of Major George Hope, late of the 77th Regiment, D.C.O., to Louise, eldest daughter of Colonel John Briggs, late of the 82nd Regiment, P.W.V.

LUCKMAN—MUIR.—On the 25th ult., at Christ Church, Timperley, by the Rev. W. Bellars, M.A., of All Hallows, London (cousin of the bride), assisted by the Rev. C. B. Gwynne, B.A., Edward Llewellyn Luckman, M.R.C.S., L.R.C.P., of Altrincham, to Fanny, third daughter of W. B. Muir, of Timperley, and niece of the late Sir W. M. Muir, M.D., K.C.B., Director-General of the Army Medical Department.

PHILLPOT—LUXMOORE.—On the 31st ult., at St. George's, Hanover-square, by the Rev. A. Thornton, LL.B., George Frederick Phillpot, M.R.C.S., L.R.C.P., &c., of Brooklands, Hemel Hempstead, Herts, third son of T. Aston Phillpot, Esq., of Summerfield House, Hartlebury, Worcestershire, to Harriett Augusta, only surviving daughter of the late William Edwd. Luxmoore, Esq., of Lawn-park, Hemel Hempstead.

DEATHS.

BLOWER.—On the 30th ult., at Duke Place, Bedford, after an illness of twenty-eight years' duration, William Blower, M.R.C.S., L.S.A., aged 84.

CORNISH.—On the 2nd inst., at East-street, Taunton, Charles Henry Cornish, F.R.C.S.E., aged 80.

CUMING.—On the 4th inst., at his residence, The Mall, Armagh, Thomas Cuming, M.D., in his 90th year.

HALLOWES.—On July 4th, at Bourke, New South Wales, suddenly, Miller Coleman Hallowes, L.S.A., in his 57th year.

JACKSON.—On the 1st inst., at Kirkbuddo, Forfarshire, James Rawlinson Jackson, Deputy Surgeon-General, I.M.D.

LOWTHER.—On the 7th inst., at 3, Nelson-avenue, Hull, George Lowther, F.R.C.S., aged 79.

OLIVER.—On the 28th ult., suddenly, at his residence, Montgomery House, Harbury, Warwickshire, Richard Owen Oliver, M.R.C.S., aged 61.

PITCHER.—On the 7th inst., at Southport, Arthur Henry Pitcher, L.S.A., eldest son of the late John Henry Pitcher, Proctor, of Doctors' Commons, in his 44th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADKINS, GEORGE, L.R.C.P.Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Plympton St. Mary Rural Sanitary District, Devon.

BOND, W. A., M.A., M.D., B.C.Cantab., has been appointed Resident Accoucheur to St. Thomas's Hospital.

BROOK, W. F., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

BULSTRODE, H. T., M.B., B.C.Cantab., L.R.C.P., M.R.C.S., has been appointed Non-Resident House-Physician to St. Thomas's Hospital.

CALVERT, J. T., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

CRISP, E. H., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

CROTHER, THOMAS, M.D. King's Col. Aberd., M.R.C.S., has been appointed Medical Officer of Health for the Midgley Urban Sanitary District, Yorkshire, vice Britton.

DUNCAN, H., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

FOX, HERBERT, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Stainland-with-Old Lindley Urban Sanitary District, Yorkshire, vice Britton.

HAWKINS, H. P., M.B., B.S.Oxon., M.R.C.S., L.S.A., has been re-appointed Resident House-Physician to St. Thomas's Hospital.

HINNELL, J. S., M.R.C.S., L.S.A., has been reappointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

HOYLE, JOHN, M.B., C.M.Ed., has been appointed Medical Officer of Health for the Barkisland Urban Sanitary District, vice Britton.

JONES, H. S., M.R.C.S., L.S.A., has been appointed House-Surgeon to St. Thomas's Hospital.

LEAH, THOMAS, M.R.C.S., has been reappointed Medical Officer of Health for the East Stonehouse Urban Sanitary District, Devonshire.

MACEVOY, H. J., L.R.C.P., M.R.C.S., has been reappointed Resident House-Physician to St. Thomas's Hospital.

MARSHALL, ANDREW, M.D., has been appointed Consulting Honorary Medical Officer to the Preston and County of Lancaster Royal Infirmary.

ORD, W. W., M.A., M.B., B.S.Oxon., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

POGSON, WILLIAM, L.R.C.P.Ed., F.R.C.S.Ed., has been reappointed Medical Officer of Health for the Leeds Rural Sanitary District.

RIGBY, JAMES A., M.D. Lond., has been appointed Honorary Medical Officer to the Preston and County of Lancaster Royal Infirmary, vice Marshall, resigned.

SMYTH, H. J., L.R.C.P., M.R.C.S., has been reappointed non-Resident House-Physician to St. Thomas's Hospital.

SISSONS, WILLIAM HARLING, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Barton-upon-Humber Urban Sanitary District.

SOLLY, E., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

TEBB, W. SCOTT, M.A., M.B.Cantab., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

TONKING, J. H., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

WHISTON, P. H., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, and washing, but no salary.

DEVON AND EXETER HOSPITAL.—House-Surgeon. Salary £120 per annum, increasing £10 a year until it rises to £150, with board and lodging.

EAST SUFFOLK HOSPITAL.—Honorary Physician.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Surgeon to out-patients.

FEMALE LOCK HOSPITAL, Harrow-road, W.—House-Surgeon. Salary £100 per annum, and board and lodging.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Obstetric Physician to in-patients.

LEAMINGTON AMALGAMATED FRIENDLY SOCIETIES MEDICAL ASSOCIATION.—Resident Medical Officer. Salary £200; £50 for conveyance; midwifery fees, &c.; good residence, coachhouse, stable, rent, and taxes free.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road, S.E.—House-Surgeon. An honorarium of £70 per annum, and board and lodging in the hospital.

SHEFFIELD GENERAL INFIRMARY.—Two Assistant Physicians and two Assistant Surgeons.

ST. LUKE'S HOSPITAL.—Resident Clinical Assistant. Board and residence.

TAUNTON UNION.—Medical Officer. Salary £75 per annum, together with fees for midwifery, &c.

TORBAY HOSPITAL AND PROVIDENT DISPENSARY, Torquay.—Junior House-Surgeon and Dispenser. Salary £80 a year, with board, lodging, and attendance (wine, spirits, beer, and washing excepted), together with fees from pupils, if any.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

"MASSAGE AND ELECTRICAL TREATMENT."

WE have received a letter from the Managing Director of the "Limited Company" referred to in an annotation which appeared in our impression of the 27th ult., page 427. The writer complains that our "strictures on Dr. Leeson are scarcely just, as he is legitimately engaged in superintending and carrying out at our establishment modes of medical treatment that, rightly or wrongly, are receiving extensive countenance from medical practitioners, and that the methods employed by him, as the Company's consulting physician, are identical with those in use by many of his professional brethren." The Managing Director evades the issue raised in our annotation. The legitimate use of electricity as a therapeutic agent is one thing; the obtrusive advertising of the name of a medical practitioner as the employer of such agent, and at the same time as a candidate for the treatment of a disease in which electricity is not specially indicated, is quite another.

Medicus.—The best text-book is Blandford's. Miller's "Hints on Insanity" is small, but good. Bucknill and Tuke's book is the standard work of reference on the subject, but probably too elaborate for our correspondent's purpose. The recent works of Drs. Clouston and Savage are excellent, but are somewhat bulky. Then there are the works of Maudsley, Esquirol, and Greisinger. Good epitomes suitable for students are to be found in Bristowe, Tanner, Russell Reynolds, and in Quain's Dictionary.

Dr. Laquer (Wiesbaden).—Arrangements have already been made.

PROFUSE PERSPIRATION.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if any of your readers will advise me in the following case.

A gentleman, apparently in perfect health, suffers great inconvenience from profuse perspiration. Walking a short distance, any slight exertion, or entering a warm room causes the perspiration literally to pour off him. He thinks this has much increased since he had syphilis and a long course of mercurial treatment three years ago. Treatment for the past twelve months has been belladonna internally and externally, mineral acids and tonics, oxide of zinc, sponging, and all the usual remedies. Belladonna externally has done good temporarily. If any of your readers can suggest any means to give him relief I shall be thankful.

I am, Sirs, yours faithfully,

September, 1887. YORK.

THE PREPARATION OF ANTISEPTIC SPONGES.

THE *Vereinsblatt Pfalzischer Aerzte* states that in the antiseptic process sponges of medium porosity are the most easily treated, those in which the pores are too fine being freed with difficulty from sand and shell-lime. They are well dried by heat, and are freed from coarse sand by being beaten with canes, being then placed upon a coarse hair-sieve, and washed until the water runs off absolutely clear and free from sediment. The sponges are then subjected to the action of a solution of permanganate of potash (1 in 1000) for about two hours, and enough crude muriatic acid is added to cause the violet colour to entirely disappear. By repeated washing with water the sponges are purified still further, until the water used in washing no longer reddens blue litmus paper. They are then well dried and placed in a solution of sublimate (1 in 1000), where they are left ten or twelve hours. By occasional washing with distilled water the solution of chloride of mercury is removed, and the sponges are then dried in a room free from dust (or, preferably, in a drying press), until no loss in weight takes place. For preserving the sponges metal vessels or wide-necked glass receptacles closing tightly are indispensable.

M.D.—Wishes to be informed of an institution in which admission may be gained, free or on payment of a small weekly sum, by a lad aged fifteen, who has crippled lower limbs. There is no affection of any other part. The intellect is bright, and his whole time is spent in reading and writing. It is thought desirable that he should learn some light trade as a means of earning his livelihood.

Ignoramus.—Dr. Lutaud, editor in chief of the *Journal du Medecine de Paris*, has published a book which gives the statistics mentioned.

Mr. J. B. Pike.—The cases are not parallel.

"PARALYSIS AFTER DELIVERY."

To the Editors of THE LANCET.

SIRS,—In reference to the letter by "Volzi" in to-day's issue, I beg to suggest that the temporary paralysis described by him might have been due to the same cause as that of "cramps" occurring both during and subsequently to labour—viz., by pressure of the child's head (especially when partially encased by forceps) on the large nerves of the lumbar plexus, causing (firstly), as a rule, cramps in the corresponding (according to position of patient—of course, usually the left) side, or rather leg; and then, if the pressure be increased, as in difficult instrumental delivery, causing partial or complete dissolution of the nerve-current, and consequent paralysis; the pricking sensation of "pins and needle" appearing when the nerves are recovering their functions. The puffiness in the ankle, I imagine, proceeds from the same pressure on the inferior cava. "Volzi" also asks if this form of paralysis is of common occurrence. I have not attended a case where the paralysis has remained so long as six weeks, but have attended within the last twelve months, out of about 200 cases, three or four, in all of which the paralysis lasted, on the average, about a week.

I am, Sirs, yours faithfully,

August 27th, 1887. EXTREME PRESSURE.

To the Editors of THE LANCET.

SIRS,—The probable explanation of the case reported by "Volzi" is that some damage was inflicted on the nerve trunks in the pelvis. Seelig-müller has published a very similar case. In the instance in question there had been a difficult instrumental labour, which was followed by neuralgic pains in the course of the sciatic nerve, and later by paralysis with atrophy of the leg. I cannot tell your correspondent if this is a common occurrence. I have had no personal experience on the point. It would be interesting to learn the experience of obstetricians.

I am, Sirs, yours truly,

Welbeck-street, W., Sept. 1st, 1887. W. B. HADDEN.

Junior Practitioner.—Information regarding the sanitary condition of Dresden may be obtained from Baldwin Latham's book. With regard to Brussels, our correspondent might apply to the Secretary of the Bureau d'Hygiène.

Mr. Palmer (Newport).—Will our correspondent state more particularly what substance is referred to under the name "gelatine emmel."

Mr. T. W. Jones (Ventnor).—Yes.

INFANTILE DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—It appears to me that one of the most cogent and common causes of the diarrhœa now prevalent among children, and of its extreme fatality among the lower classes, is not sufficiently discussed in your influential columns. While straining at gnats do we not swallow camels in neglecting to inform the public of the dangers arising from the indiscriminate use of green and unripe fruits, especially by children who have as yet not all their teeth? One does not nowadays enter a tramcar or pass a perambulator without seeing an infantile occupant discussing a green apple or an unripe plum, fed to its destruction by its misnamed "nurse" or ignorant mother.—I am, Sirs, yours sincerely,

London, Aug. 28th, 1887. PÆDIATRIX.

THE STUDENTS' NUMBER: ADDENDA ET CORRIGENDA.

IN the list of lecturers at the London Hospital which appeared in our Students' Number the name of Dr. Lewers, Assistant Obstetric Physician to the institution, was inadvertently omitted. The names of the professorial staff of Queen's College, Birmingham, were also incorrectly given. They should read as follows:—Medicine: Sir Walter Foster, M.D., F.R.C.P., M.P.; Sir James Sawyer, M.D.Lond., F.R.C.P. Surgery: Oliver Pemberton, F.R.C.S.; Bennett May, M.B., B.S.Lond., F.R.C.S. Anatomy: Bertram C. A. Windle, M.A., M.D., B.Ch.Dub. Demonstrators of Anatomy: Jordan Lloyd, M.B., M.S., F.R.C.S.Eng.; W. F. Haslam, F.R.C.S.Eng.; F. Marsh, F.R.C.S.Eng. *Systematic Physiology: F. J. Allen, M.A., M.B.Cantab., M.R.C.S. *Chemistry: William A. Tilden, D.Sc.Lond., F.R.S. *Chemical Physics: W. Poynting, M.A., D.Sc.Cantab. Pathology: Gilbert Barling, M.B., B.S.Lond., F.R.C.S.Eng. Demonstrator of Medical Pathology: Arthur Foxwell, B.A., M.B.Cantab., M.R.C.P. *Histology and Practical Physiology: F. J. Allen, M.A., M.B.Cantab., M.R.C.S. *Botany and Vegetable Physiology: William Hillhouse, M.A. Cantab., F.L.S. *Practical Chemistry: W. A. Tilden, D.Sc.Lond., F.R.S. Materia Medica and Therapeutics: Edwin Rickards, M.A., M.B. Oxon., F.R.C.P.; C. W. Suckling, M.D.Lond., M.R.C.P. Forensic Medicine: J. St. S. Wilders, M.R.C.S. Toxicology: A. Bostock Hill, M.D., F.I.C.S., Sc. Cert. Cantab. Midwifery and the Diseases of Women: John Clay, M.R.C.S. Practical Surgery: Demonstrators—Vacant. Ophthalmic Surgery: J. Vose Solomon, F.R.C.S. Lunacy and Mental Diseases: E. B. Whitcombe, M.R.C.S. Curator of the Museum: Bertram C. A. Windle, M.A., M.D., B.Ch.Dub. Medical Tutor: E. Hogben, B.A., M.B., B.Ch.Dub., M.R.C.P.Lond. The classes marked * will be held in Mason Science College.—In the table showing the rates of pay, &c., in the Army Medical Service, which appeared on page 472, the words "relative military rank" were by an oversight printed in place of "ranks as."—We are also requested to state that the practice of the Birmingham and Midland Orthopædic Hospital is open to students of the Birmingham School of Medicine.—Post-graduate courses of lectures—i.e. lectures only open to legally qualified practitioners—are delivered in connexion with the Charing-cross Hospital Medical School and the Leeds General Infirmary; also at Edinburgh.

Mary E. Johnson.—We must refer our correspondent to our advertising columns, or to the Charities Register and Digest, published by Longmans.

Mr. J. C. Murphy.—We are not in possession of any information on the subject beyond that contained in our advertising columns.

Mr. J. H. Potter.—1. It is not possible to answer this question.—2. Not at all likely.

E. F. Lee had better submit the matter to her ordinary medical attendant.

"SWEATING OF THE FEET."

To the Editors of THE LANCET.

SIRS,—Dr. Taylor* states that he has found a remedy for sweating of the feet in borate of soda. I would venture a theory. Has not the oleaginous exudation from the feet more affinity to the soda than the boracic acid, thus rendering it more soluble? Would your correspondent be kind enough to apply the soda and the borax separately, and thus prove which is most efficient? Has the decline of the hot weather anything to do with the cure by salicylic acid? In my case, at present under treatment, alum was tried and found ineffectual, whereas soda has proved a complete success. No remedy I believe will suffice to prevent its recurrence during the hot weather.

I remain, Sirs, yours truly,

Newhaven, Aug. 30th, 1887. D. RICHARDSON, M.R.C.S., L.S.A.

* The signature was misprinted. It should have been "J. Slight, M.D."—ED. L.

To the Editors of THE LANCET.

SIRS,—Permit me to mention two methods of treating the above complaint which I have found perfectly successful. One is the use of a dusting powder consisting of 15 parts boracic acid, 25 parts oxide of zinc, and 60 French chalk, applied freely to the socks as well as to the feet. The other method is to apply Barff's boroglyceride after carefully drying and rubbing the feet. In this way a slight case was cured in four days. Special attention should be paid to the skin between the toes.

I am, Sirs, yours faithfully,

Finsbury-circus, Aug. 26th, 1887. F. R. WALTERS, M.D. Lond.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Please allow me to acknowledge the following contributions to the above fund:—Dr. Wyman, £2; Dr. B. Hamilton (Dublin), £1 1s.; T. E. Bowkett, Esq., 10s.; Dr. W. Laidlaw Purves, 5s. Amount previously received, £34 17s. I am, Sirs, yours faithfully,

G. STANLEY MURRAY, M.D.

23, Upper Richmond-road, Putney, Sept. 6th, 1887.

SNAKE-FARMING FOR PHARMACEUTICAL PURPOSES.

A WRITER in a newspaper having expressed surprise at anyone attempting to farm rattlesnakes, as at least one man in America does, and having asked what can be the use of a dead rattlesnake, the *Monthly Magazine of Pharmacy* remarks that it is evident that the writer is unaware that the homœopaths make use of the poison of the rattlesnake under the name of "lachesis," which drug, indeed, was said by a homœopathic journal not very long since to have caused the death of a patient, an overdose having been taken. The *Magazine* then goes on to supply some interesting information with respect to the rattlesnake trade. The breeder, who is anything but a mythical individual, has, it seems, a farm of forty acres in Illinois, where he grows snakes by the thousand. His land has never been ploughed, and is devoted entirely to this "odd sort of agriculture." It is interesting to know that the contract price for "rattlesnakes' tails in bulk" is £1 per tail, and that a pharmaceutica firm in Philadelphia contracts to take 250 tails every year. We have given the wholesale price at which the product is quoted, for it is never retailed, any more than the serpents themselves, the extract called lachesis being the ultimate object of rattlesnake rearing. With regard to the enterprising breeder, an American correspondent writes: "Unless he has learnt the art of snake-charming, that Illinois farmer will probably take a look at his stock once too often."

An Old Subscriber.—The first arrangement was the best; but in both the interval between the last meal in the evening and the first meal in the morning is too long. The serving out some small refreshment on rising is a good plan; but in addition we would advise a light supper of some kind. The following is the dietary that has frequently been adopted on our recommendation, and found to act well:—6.30 A.M.: Cup of milk and piece of bread. 8.30: Breakfast, with eggs, fish, bacon, cold meat, &c. 1.30: Dinner. 6 P.M.: Tea, with preserves or butter. 9 P.M.: Supper, bread and cheese, or porridge, or cup of hot milk with slice of bread.

Nemo can only obtain answers to such questions by addressing them specifically to club surgeons on a large scale.

Surgeon.—Our correspondent should address his question and a copy of the advertisement he sends us to the Dean of the Medical Faculty of the University of Edinburgh.

Mr. J. H. Parkinson (Sacramento).—We are unable to extend our exchange list at present.

CASE OF DISLOCATION OF BOTH HIPS; DISLOCATION OF RIGHT SHOULDER, AND FRACTURE OF TWO RIBS; RECOVERY.

To the Editors of THE LANCET.

SIRS,—Possibly the following case may be interesting to the readers of THE LANCET:—

I was called in to attend G. S——, a collier, aged thirty-six, on July 31st, 1886. Whilst at work on that date a fall of the roof took place just above where he was working, striking him on the back of the neck and doubling him up. His companions state that quite a ton of earth fell upon him. He was brought home quite unconscious. I was sent for, and found the above-named injuries. The right leg, which was dislocated on to the pubic bone, was reduced the first, whilst the man was partially unconscious. This was reduced by extension backwards and outwards, and a napkin used for counter extension. After extension had been kept up for about ten minutes, the head of the bone slipped in. The left leg was then taken in hand, but, from the severe struggling of the patient, could not be reduced without chloroform. After placing him thoroughly under its influence I attempted the reduction (this was on to the dorsum ilii). By bending the knee and flexing the thigh, and giving it a rotatory movement, at the same time having counter extension used with a napkin, I had the satisfaction of finding this joint easily reduced. I then, before the patient became conscious, reduced the dislocation of the shoulder, which was subcoracoid. I then attended to the injury of the ribs. The patient made a good recovery, being up and walking about in fourteen days, and at work in ten weeks. He had some stiffness in his shoulder, which prevented him from using his arm before the end of that period. Since then he has followed his usual occupation. I am, Sirs, yours faithfully,

September, 1887. SURGEON.

Mr. Samuel Coates must act on his own sense of what is right and dignified in the case. He should have no further dealings with the parties referred to.

S. M. Hadi.—Both of the physicians named are deceased.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me what the chances of experienced, hospital-trained, reliable private nurses are in Sydney or other Australian cities—whether much in demand or not?

I am, Sirs, yours obediently,

Sept. 3rd, 1887. J. C.

A CATERPILLAR IN THE NOSE.

To the Editors of THE LANCET.

SIRS,—A woman complained of pain, irritation, and stuffiness of the right nostril; the symptoms came on suddenly, and were very troublesome, she often experiencing a sensation as of something about to go down the throat. Nothing, however, was to be seen. In a few days a bloody purulent discharge was set up, and in about a week's time on blowing the nose she dislodged a caterpillar, experiencing immediate relief; it was about an inch long and half an inch in diameter. The legs were perfectly developed, tail bifurcate, with a fleshy mass half an inch long projecting from it (I suspect from injury); the insect seemed to be much dwarfed and shrivelled, with head disproportionately large to body. It lived some hours after being expelled from the nose, and was then brought to me. I ordered the nostril to be syringed with boracic lotion, and conclude the recovery was speedy and complete, having heard nothing more of the woman. I may remark that the cottage in which she lived was densely overhung with Virginia creeper, whence I have no doubt the insect primarily issued. I am, Sirs, yours faithfully,

Aug. 24th, 1887. GOOD.

Assistant.—We think B is entitled to make strong representation that he did not contract to do locum tenen's work, and has a reasonable claim to extra remuneration for such work.

CORRIGENDUM.—In Dr. Yule's article, "Chronic Hypertrophic Cirrhosis of Liver," Aug. 27th, p. 413, for "altering venous blood in other systems before it is arterialised" read "the liver likewise alters the venous blood of the whole body before it is arterialised."

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Lectures
ON
PRACTICAL LEGAL MEDICINE.

Being the Post-Graduate Course delivered at St. Mary's Hospital,

BY AUGUSTUS J. PEPPER, M.S. LOND.,
LATE EXAMINER IN FORENSIC MEDICINE TO THE UNIVERSITY OF LONDON.

LECTURE II.

SPECIAL POST-MORTEM EXAMINATIONS.

GENTLEMEN,—My lecture to-day will treat of a series of special post-mortem examinations, made for the purpose of supplying evidence before a legal tribunal. I speak of them as special on account of some mystery which surrounded the death; or because unusual care was required in the necessary manipulation; or, lastly, because the facts ascertained were liable to doubtful interpretation. Our system of teaching forensic medicine is, according to my experience, singularly faulty, excepting the toxicological section. I do not remember to have seen a post-mortem examination made in the schools with the object of illustrating questions that might arise in civil suits or criminal trials. This defect in the curriculum of medical education I have found, as examiner, reflected by the answers of candidates at examinations. The application of medical knowledge to the administration of justice is one of the highest functions of our profession, and yet the practitioner is left to acquire his education in applied legal medicine after he has become qualified. Apart from the knowledge of poisons, most of our examining bodies require very scanty proof of the candidate's acquaintance with practical jurisprudence. It is no wonder, then, that many mistakes are made in medico-legal investigations. I have frequently been impressed, when demonstrating some particular method of examining the cadaver, by the remarks of medical men that whilst students they had learnt so little of the subject. It is to be hoped that ere long the neglect here complained of will be remedied.

We will take for our first study the question of *criminal abortion*, and discuss the post-mortem procedure for its elucidation. Now, if we exclude the effects of mechanical injuries and the detection of abortifacients, there are no signs which would warrant a medical man in saying that an abortion had been criminally induced or attempted. The ascertainable causes of natural abortion are numerous, and beyond this there is a large residuum of cases which it is wellnigh impossible to explain by examination of the dead body. In giving evidence, therefore, it is necessary to be very guarded in stating an opinion. The necropsy is performed in order to determine—(1) whether an abortion has taken place; (2) in that event, whether naturally or criminally. Careful inspection should be made of the external genitals, and of the adjacent parts of the buttocks, thighs, and abdomen, to see if there be any punctured wounds; for the criminal abortionist, being either unskilled or acting with trepidation, often inflicts injuries unnecessary to his purpose. Moreover, the uterus has been intentionally punctured through the abdominal wall. Do not make a digital or instrumental examination of the vagina *in situ*, for the information you would gather thereby would be limited, and you are liable to make abrasions which would complicate further inquiry. Open the abdomen by a longtitudinal incision, and divide the recti muscles at their insertion, so as to give ample view of the pelvic contents, and to avoid rough handling of the latter. Put a double ligature on the lower part of the sigmoid flexure. Note the presence and degree of peritonitis, pelvic cellulitis, or pelvic adhesions, old or recent. Search for a punctured wound of the anterior wall of the uterus, and for the correspondence of such with a puncture of the abdominal wall. The uterus and its appendages, the rectum and bladder, are to be removed *en masse*. If the pregnancy has not advanced beyond the third month (I am assuming that the womb has not been emptied), there will be no occasion to do more than to divide the soft structures binding the aforesaid viscera to the pelvis, to make externally an incision surrounding the vulva and rectum, and then to free the entire mass by passing the knife around the pelvic outlet, keeping the edge directed outwards. By gentle traction the structures thus detached can be lifted without injury from the pelvis. If the pregnancy is further advanced, it is better to saw through the pubic bones outside the spinee, for the uterus impinges on the pubic crest, and in trying to make the subpubic incisions you would have to pull the uterus upwards, and this might entail rupture of the membranes or laceration of the placenta—a mishap I once witnessed. Now lay the parts removed on a clean slab or dish, with the bladder upwards. Take a pair of scissors with shot-guarded points and open the bladder by a median incision, and the vagina in like manner. Examine the latter for foreign bodies, for any discharge, and for punctures or lacerations. Cleanse the mucous membrane by a stream of water, and not by wiping or scraping. Note the character of any wounds, and make an incision through them to ascertain the depth to which the blood has been extravasated. A wound made accidentally during the examination will be free from hæmorrhage in the tissues around it. Do not forget that the vagina may be wounded by a legal procuration of abortion; by an attempt to extract the products of conception in an abortion naturally commenced; or by the use of instruments for examination of the passages or for cleansing them. So, too, the os uteri may be lacerated by parturition. But the wounds inflicted in criminal abortion are commonly punctured, and, if lacerated, they are usually far more extensive than would be caused by lawful manipulation. The criminal abortionist, I repeat, generally uses greater violence than is necessary to accomplish the ends he has in view. Next, the cavity of the uterus should be opened by a median longitudinal incision with the blunt-pointed scissors. Examine what contents there may be, noting particularly any laceration or detachment of the placenta; then carefully remove the contents and look for injuries of the uterine wall, and note if they correspond in direction with similar injuries of the vagina or cervix. In July, 1884, a woman was admitted moribund into University College Hospital. Before admission she had been attended by a nurse, and the medical man in charge suspected typhoid fever, for there had been profuse diarrhœa, with pain and swelling of the abdomen. Before the doctor saw her the hæmorrhage of abortion had been construed as profuse menstruation. I assisted at the post-mortem examination. There were punctured wounds of the skin on each side of the vulva. There were punctured and lacerated wounds of the labia and vagina. The posterior lip of the os uteri was bruised. The uterus, which with the ovaries attached weighed thirteen ounces, was empty. There was a large, circular, sloughy, raised surface on the posterior wall, the placental site; on the anterior wall there was a smaller elongated sloughy patch, as if the tissue had been ploughed up. In a line with this there was a linear laceration of the cervix. All these wounds had been inflicted during life. At the inquest the jury returned an open verdict. The case is instructive in many ways: the simulation of natural disease, the failure of detection of the real condition, and lastly, the gross outrage which had been committed.

If the abortion has been procured at an early date—that is, under the third month,—and the uterus has been entirely evacuated, it might be contended at the inquest or trial that pregnancy had not occurred, but that the enlargement of the uterus was due to disease of its structure. Even in these cases you will rarely fail to establish the facts independently of non-medical evidence, circumstantial or direct. If the placenta has only just formed, you may find portions hanging like fringes at the site of attachment. At an earlier date you will see a circular patch where the mucous membrane is flocculent from villosity, or, if smooth, it will be more vascular than the lining membrane of the uterus generally. This was the condition of the uterus in the Turnbull case tried at the Central Criminal Court on January 15th, 1886. If there is peritonitis, search for wounds of the pelvic peritoneum. The inflammation, however, has generally spread in continuity from the uterus along the Fallopian tubes, in which event the latter will contain purulent fluid. There may be pelvic cellulitis or abscess with or without peritonitis. You will of course look for signs of blood-poisoning in distant parts. Turnbull was committed for trial for having illegally procured abortion on two women—Clifford and Burton. At the post-

Digitized by Google

mortem I found purulent peritonitis in the one case, and pelvic abscess in the other.

If practicable, examine the ovaries for a *corpus luteum* before removing the viscera from the pelvis. Our principal text-books on Forensic Medicine—Guy and Taylor—appraise with very different values the corpus luteum as trustworthy evidence of recent pregnancy. Taylor, although admitting that the corpus luteum undergoes a higher development if conception takes place, argues mainly to the end that there are too many exceptions to the general rule to allow of its being considered of much worth, save by way of corroboration of the evidence afforded by other signs of pregnancy. The view just stated is the one which prevails with the majority of medical jurists, who maintain that in the early stages of pregnancy the corpus luteum is not sufficiently distinctive, whilst at a later period it is not required, since there are other signs of greater import. From a number of observations, I feel inclined to attach greater weight to the corpus luteum. In the case of the woman Clifford the pregnancy had advanced two and a half months; the uterus was found to have been entirely emptied of the products of conception, and I can conceive that the question of pregnancy from an examination of the uterus alone might have been challenged, but in the right ovary there was a deep orange-coloured corpus luteum five-eighths of an inch in diameter,—a development I believe to be inconsistent with the theory of changes dependent simply on menstruation. The absence of the usual growth of the corpus luteum may not be of much value as a negative sign; for in the woman Burton, although pregnancy had reached the end of the third month the corpus luteum was insignificant, its growth having been impeded by fibroid induration of the ovarian capsule.

Of course, you will not fail to examine the rectum for foreign bodies, for the effects of irritant or corrosive poisons, and for signs of mechanical injury. Criminal abortion by mechanical means is sometimes induced by self-injury, and it may be by the use of some such instrument as a skewer or knitting-needle. Now, although the mutilation of the parts cannot with certainty be told from injuries inflicted by another person, there are some points that might justify you in giving an opinion, and even a strong one, as to the probability of its source. If the punctures are confined to, or mainly situated in, the posterior wall of the vagina, they are not unlikely to have been made by the woman herself, and if at the same time the uterus is free from all evidence of violence the view just enunciated is greatly strengthened. If the abortion had been induced by a medical man, there would in all likelihood be an absence of grave vaginal injuries; and, assuming their presence, they would, I believe, be accompanied by uterine punctures, lacerations, or abrasions. If the abortion had been procured by an ignorant and unskilful person other than the victim, the injuries would probably be greater than a woman would be likely to inflict on herself. The testimony you could give in such a case, considered apart from collateral evidence, would not justify a coroner's jury in returning a verdict of murder or manslaughter, but it would warrant them in leaving the question an open one, and so recording it.

I will now direct your attention to the *examination of the cranium and its contents*. No other part of the body affords greater scope for careful discrimination of the results of injuries and disease. If you hold a skull up to the light, the cranial vertex having been removed, you will see that it is translucent at the orbital roof and in the temporal and cerebellar fossæ, and hence that in these regions it would be easy to fracture the bone. Such injuries would be more frequent than they are but for the natural means of protection. The cerebellar plate is guarded by a mass of muscles at the back of the neck, the squamosal bone is covered by the temporal muscle, and the orbit is shielded by the organ of vision. The brain may be penetrated by accident or design by a thrust through the roof of the orbit, so look for a punctured wound beneath the upper eyelid. It is common knowledge that death is not rarely caused by blows on the temple, the brain being lacerated by splinters of bone. At an assize trial a man was convicted of manslaughter by striking his victim on the temple. It was urged in mitigation of punishment that the skull was unusually thin. The medical man who gave evidence stated that at its thinnest part it was no thicker than a sixpence, a condition I believe not far removed from the average. The mistake thus unconsciously made enabled the prisoner to get off with a light punishment. Whenever death is supposed to be due to an intra-cranial lesion, it is better to begin the post-mortem examination by removing the skull-cap and dissecting the brain and its membranes, for if the large veins of the neck or thorax be wounded, the blood drains off from the venous sinuses, and so their degree of fulness would be altered. Having done this, search for fracture of the bone, and for wounds or inflammation of the dura mater. Do not forget that a blow on one side of the head may injure the brain and its coverings in the immediate vicinity, or at the opposite point by *contre-coup*. On reflecting the dura mater, see if there be intra-arachnoid adhesions, suppuration, or hæmorrhage. The last is not uncommon in children dying at birth, or at a later period in chronic wasting disorders. It may also result from fierce mental excitement, even in the adult, though in these cases I suspect the vessels are in some way diseased. From these data you will be careful not to assign this form of extravasation as necessarily due to injury. The Pacchionian glands vary in size according to the age of the individual; in one instance where they were very large they were mistaken for "tumours of the brain," and they were so described in my presence. When very small they may be confounded with miliary tubercles, and it is the belief of some that they were so in the case of Mrs. Staunton—historically known as "the Penge mystery." Tubercular meningitis limited to the vertex is very rare. Moreover, the Pacchionian glands are mere outgrowths from the arachnoid; they have no intimate connexion with the pia mater. There are few cases in which the convolutional veins are not well filled in the cadaver, especially the large ones at the posterior part of the brain, where the congestion is largely owing to gravitation. It is only after considerable experience of necropsies that one is able to affirm that such congestion is indicative of particular obstruction to the cerebral circulation during life. Clearly these veins will participate in the congestion of the venous system generally; e.g., in all forms of asphyxial death; this was noted in my first lecture. But there are many causes of unwonted distension of the cerebral veins of local origin—notably in thrombosis of the lateral sinus and in every variety of meningitis. If there is great excess of fluid in the lateral ventricles, the cerebral convolutions will be flattened by pressure against the skull, and the corpus callosum will be arched to a corresponding extent. To ascertain the amount of fluid, puncture the roof of the ventricles and draw off the fluid with a syringe.

This is a fitting occasion for studying the question of *intra-cranial suppuration*. Pus between the bone and the dura mater arises from injuries to the head, and in some cases from disease of the middle ear. In the latter affection, however, the dura mater is seldom detached to any great extent, but it is common to meet with diffuse arachnitis and pia meningitis, and even cerebral or cerebellar abscess. Suppurative arachnitis is usually the result of injury, ear disease, syphilitic inflammation of the bone, or pyæmia. It is highly important not to confound suppurative arachnitis with widespread effusion of puro-lymph beneath the pia mater and within its meshes. The latter form of meningitis is met with in tuberculosis when it is chiefly basal; it also occurs as an idiopathic disease in very young children, and may be set up from some distant local centre of infection; but, as already said, pyæmic meningitis involves chiefly the arachnoid. There is one exception—viz., where it has arisen in consequence of pyæmic abscess in the brain. I have examined two cases of purulent arachnitis following closely in the wake of vaccination. In both, from want of proper care and cleanliness, unhealthy ulceration had spread from the vaccination sores, and at the inquests I deposed that death arose from pyæmic inflammation of the arachnoid. In the former case this conclusion was assailed by high authority, as it was considered as not proved that the meningitis was not idiopathic in nature; but I think that the discrepancy of opinion is explained in that the traversers had in mind pia meningitis, and not arachnitis, which really occurred. The second case substantially supported this view I had taken of the former; for besides suppurative arachnitis there were abscesses in the cellular tissue and in many joints. One of the medical inspectors of the Local Government Board agreed that these multiple lesions were to be traced to absorption of septic matter from the ulcers in the arm. No one believes more strongly than I in the efficaciousness of vaccination as a life-saving institution, that the unfortunate events just referred to are not in any way owing to vaccination *per se*, and, further, that they are wholly preventable.

At an inquest held in March, 1886, I was requested to give evidence in the case of a man who had died from meningitis nine weeks after he had met with a railway accident. The issue was the more important because it involved the question of compensation. At the necropsy I found advanced phthisis, tubercular epididymitis, and tubercular meningitis. The main question to be decided was how far the accident might have accelerated death. I stated it was possible that the injury might possibly have been a local exciting cause of the meningitis, but under any circumstances there could have been but a short tenure of life.

[The lecturer's remarks on criminal abortion were illustrated by preparations taken from cases that had been the subject of judicial inquiry.]

A CONTRIBUTION TO THE PATHOLOGY OF THE BLOOD.

BEING AN ACCOUNT OF CERTAIN CRYSTALLINE CHANGES OCCURRING IN THE HÆMOGLOBIN AFTER WITHDRAWAL FROM THE BODY, IN THE SUBJECTS OF CERTAIN DISEASES, ESPECIALLY THOSE OF SEPTIC ORIGIN.

BY C. J. BOND, F.R.C.S.,
SURGEON TO THE LEICESTER INFIRMARY.

PART II.

WE have now to consider the condition of the blood in those diseases, or rather aggregation of symptoms, associated with the presence in the blood or tissues of substances or chemical products, not owing their origin to the life-history of micro-organisms. These conditions fall into two divisions: one in which the substance or poison is introduced from outside, as in the case of a patient saturated with ether; and another in which the poison is produced in the body by disturbed or perverted metabolism and nutrition, as in the case of jaundice or uræmia. Now, as, indeed, we should expect from previous considerations, we find that, taken as a whole, the crystalline tendency is absent in all these cases.

Thus, in the first division, it is absent in the blood of patients who have been long under the influence of ether or chloroform. As a rule, it is absent in cases of opium poisoning. In one fatal case, however, slight crystallisation appeared after the blood had remained on the slide for forty-eight hours, and in this case the man had been in a state of complete coma or semi-asphyxia for twelve hours previously.

The second division will next be considered.

Rheumatic Fever.—The crystalline tendency is absent even in well-marked cases, with a temperature of from 101° to 104°. In one case of hyperpyrexia, however, in a syphilitic subject, in which the temperature rapidly rose from 99° to 107°, it was interesting to note that at noon, the temperature being 107°, a drop of blood showed the crystalline change well after standing fifteen hours; whereas at 9 P.M., after energetic treatment with the ice pack, when the temperature gradually fell to and remained at 99°, a drop of blood only showed a very slight crystalline change after standing forty-eight hours; and two days later, the temperature still being 99°, no change could be detected even after standing two or three days. The only explanation of the presence of the crystalline change in this case of extreme pyrexia is that it occurred in a patient who was suffering at the time from paraplegia due to syphilitic disease of the cord, and the sudden rise of temperature may have been due to further nerve influence, and not to chemical poisoning.

Rheumatoid Arthritis.—The crystalline tendency is absent in these chronic cases.

Uræmia and Uræmic Coma.—I have examined the blood in many cases of Bright's disease terminating fatally in coma or convulsions, and have never detected the crystalline tendency. Here the evidence is strong that the symptoms are due to some partially oxidised products of tissue change circulating in the blood, and the absence of crystallisation is worthy of notice.

Diabetes.—The blood in two cases of ordinary diabetes in which large quantities of sugar were passed daily showed no change. In two cases of diabetic coma or acetonæmia, fatal in from thirty to thirty-six hours, very slight crystallisation occurred after the blood had remained five days, and in another case of diabetic coma it was absent.

Jaundice.—We are only dealing here with jaundice as a certain symptom or condition of the system due to the retention of a certain substance or substances, and not with reference to the disease producing it. In simple cases of jaundice, due, for instance, to catarrhal obstruction of the duct, I have never detected any crystalline change in the blood; on the contrary, the presence of bile salts in the blood seems to lessen the usual amount of exudation of the hæmoglobin out of the corpuscles into the serum after withdrawal.

We may assume, therefore, from these facts, that the presence of chemical substances in the blood, which, like sugar in diabetes, or the nitrogenous bodies in uræmia, or the supposed lactic acid in rheumatic fever, or the bile salts in jaundice, are not formed by the growth of vegetable micro-organisms, is not in itself sufficient to produce this crystalline change in the hæmoglobin.

The following diseases are due to pathological change in the blood or certain organs not yet demonstrated to be due to micro-organisms.

Anæmia.—This is the condition in which, above all others, we should anxiously look for this crystalline change. It is, of course, however, necessary to distinguish carefully between the different diseases included under this name. In idiopathic anæmia or chlorosis, so common in young women, the blood has been examined in severe cases, and no crystalline tendency detected. This disease being probably due to a defective formation and supply of red corpuscles, it is interesting to know that those corpuscles which are in circulation have not that peculiar tendency to degeneration which leads them to crystallise after withdrawal from the body.

Anæmia from Hæmorrhage.—Here, too, there is no crystalline change; the corpuscles which remain appear healthy.

Pernicious Anæmia.—Four well-marked cases of this disease were examined repeatedly, and they present some interesting points of contrast. In two cases the blood contained only 50 per cent., or only half the normal numbers of red corpuscles, and these were badly shaped, and 23 per cent. and 50 per cent. respectively of the normal amount of hæmoglobin. Both patients had been ill for a long time, and had received no benefit from taking iron. Both recovered after taking arsenic for about two months, and in both cases the temperature was normal throughout. In neither case was any crystallisation detected in the blood. In two other cases, one a girl aged sixteen, and one a man aged thirty-six, the symptoms were alike, but differed from those in the last two cases. In both there was at times sickness; both had relapses, relieved by arsenic, made worse by iron. In the man's case, he had an illness of the same kind a year previously, for which he took arsenic. He died eventually three months after leaving the hospital, probably from the same disease. The girl ultimately recovered. In both cases the temperature was constantly above normal, and occasionally ran up to 102° and 103°. In both there was the crystalline change in the blood; this disappeared in the girl's case as convalescence came on. In the man's case, a marked relationship existed between the amount of crystallisation of the blood and the amount of arsenic taken. Thus, it was found that after the arsenic had been taken for one week there was only slight crystallisation after the blood had stood five or six days, and eventually none at all. Whereas, if the arsenic were discontinued for some days, crystallisation reappeared after the blood had stood from twenty-four to forty-eight hours, and this association was repeatedly tested. These facts point to the suggestion that cases of pernicious anæmia are not all alike in their pathology; they differ in the important respects of temperature and crystalline degeneration in the blood-corpuscles. Moreover, cases in which these latter symptoms exist are more severe, and seem to have some of the appearances seen in cases of septic poisoning. The poverty of red corpuscles in this disease appears, according to recent researches (Hunter, Radcliffe, Oliver, &c.), to be due to an excessive destruction of these bodies in the liver, and perhaps in other organs; whether this is due to the agency of micro-organisms or to a peculiar action of the hepatic cells is not settled, and the arsenic may either act on the red corpuscles, or, as is more probable, on the liver cells themselves. It is also interesting to note that in one case the patient had previously suffered from jaundice. What the real difference is, if any exists, in intimate pathology between these two groups of cases cannot be at present demonstrated; it may be one only of

Digitized by Google

degree of destruction of red corpuscles; but from our previous knowledge of the conditions under which crystallisation occurs in the blood, we should have been led to expect the presence in the blood of the latter group of cases of some poison or ferment associated with the growth of micro-organisms.[1]

Addison's Disease.—In two well-marked examples of this disease the blood was found to crystallise in from twenty-four to forty-eight hours after withdrawal, and the change was more marked the more severe the anæmia and debility—the nearer, in fact, to the fatal termination. It is, of course, well known that the blood is much changed in Addison's disease, the red corpuscles being diminished in number and misshapen; and now we see that, in addition, there is a tendency for its hæmoglobin to crystallise. The cause of this change, like that of the bronzing of the skin and the anæmia, is unknown, but may very probably be closely associated with these, perhaps having with them one common cause. It is, however, interesting to note that, as in the case of pernicious anæmia, the crystalline change bears some direct relation to the temperature, which varys irregularly in this disease.

Splenic Leucocythæmia.—It was the well-marked manner in which crystallisation occurred in the blood of persons suffering from this disease that first drew my attention to this subject. Indeed, it has been noticed by previous observers that after death the hæmoglobin readily crystallises in the blood of such patients. The crystals appear on the slide not only in the red corpuscles, but also in the form of large plates in the exuded hæmoglobin. Now, at once it is right to state that there is evidence to show that the crystallisation is due to the presence in the blood of the leucocytes in large quantities, and not to any primary change or degeneration in the red corpuscles. This point will be discussed later, but this statement applies to cases in which the spleen is the organ solely or chiefly enlarged, and in which there is marked leucocythæmia; and it receives confirmation from the fact that in well-marked cases of Hodgkin's disease, in which the lymphatic glands may be enormously enlarged, but in which there is no marked excess of lecocytes in the circulation, crystallisation does not occur.

Tumours or New Growths.—For the purpose of this inquiry cases of tumour or new growth must be classified not according to their embryonic or histological characters, but may best be divided into two large divisions. 1. Cases in which the new growth is very vascular, rapidly growing, and situated in parts where rapid infiltration of surrounding tissues can occur, as in the case of internal organs, especially the liver. This group will include such forms as the soft round-celled sarcomata and the encephaloid carcinomata. 2. Cases in which the new growth is only moderately vascular, slowly growing, and more or less defined or limited in outline. This will include the non-malignant forms, and such cases of malignant disease as epithelioma, scirrhus, &c. In viewing tumours, moreover, in their relation to this blood change, we must exclude cases in which there is any possibility of septic poisoning by ulceration or peritonitis, &c., and also all cases in which there is a marked increase in the number of leucocytes in the blood, since we have reason to believe that, as in the case of splenic leucocythæmia, these bodies are capable of themselves producing this change. Further, the blood examined must be drawn from the finger or some convenient spot away from the tumour, for—and this point is very important—if a drop of blood be obtained by a hollow needle directly from a rapidly growing vascular new growth, and placed on a slide, it will of course contain numbers of cells and tissue elements from the tumour itself. Now such blood so treated and allowed to remain will show the crystalline change well in from twenty-four to forty-eight hours. In fact, the cells of the neoplasm seem to act in contact with the red corpuscles, in the same way as the leucocytes in splenic leucocythæmia. Bearing these conditions in mind, I have found that in several cases included in Group 1, one a case of encephaloid of the liver, and one of lympho-sarcoma of the mesenteric glands, the crystalline change exists. Further, such cases in the course of the disease show at times irregular rises of temperature, reaching it may be 100° or 101°, and lasting perhaps a few days, or for longer intervals. It is in these cases that the change is most marked, and in one case was limited to the pyrexial periods and absent when the temperature was normal. In the case of Group 2, on the other hand, I have failed to detect crystallisation even in cases of so-called cancerous cachexia when due to such tumours as scirrhus of the breast.

With regard to an explanation of these facts, we may at once assume that it is not by virtue of their malignancy alone—that is, by virtue of their being sarcomata or cancers—that these growths produce this result; for if a tumour composed of muscles or leucocytes had the same vascularity, the same rapidity of growth, it would probably produce the same effect. Further, the general volume of the blood seems to be affected, as we have seen, only in cases under Group 2, and in these only at a late period of the disease. The production of this blood change seems to be clearly connected in some way with the rapid cell growth and cell decay, the tissue change, and the increased metabolism which is going on at the site of the growth, and which produces its effect primarily on the blood circulating in the tumour. May not, in fact, the occasional elevation of temperature, alike with the crystalline degeneration of the red corpuscles, point to the liberation at this spot of some chemical product, the result of the rapid growth, decay, and death of these cell elements? Knowing, as we do, that blood left in contact with the tumour cells crystallises readily, even when a drop drawn from the general circulation shows no change, we may explain the absence of the crystalline change in slowly growing tumours, and in many cases of malignant disease, on the supposition that, the breaking up and elimination of red corpuscles being active, the rapidity of growth and change at the site of the tumour is not sufficient to influence the whole volume of the blood. At all events, looked at from this standpoint, I think that a little light is thrown on the relation of the life of the tumour to the life of the individual, and on the influence of their rapid growth on the general nutrition, and the way in which they produce general blood change, anæmia, and death.

No mention has yet been made of cases of high temperature due primarily to neurotic influence. Thus the blood has been examined in cases of marked pyrexia reaching 106° or 107° coming on suddenly after injury to the spinal cord high up in the neck; but this condition has been so transitory, the patients dying so soon, that I have not been surprised at the non-detection as yet of any crystalline change, especially when we bear in mind the probable absence in these cases of poisoning in the septic sense of the word. I have also failed to observe it in cases of rapid and transitory rises of temperature with rigors, following the passage of catheters &c., when due to reflex irritation, and not absorption of septic matter.

The Influence exercised by Local Conditions on the Blood in respect to this Crystalline change.—By local conditions are meant alterations in the tissues of any part of the body in which the blood circulates, such as a lowered vitality or death due to mechanical or chemical causes. We have already seen that blood from a case of splenic leucocythæmia, containing as it does such numbers of leucocytes, crystallises markedly; also that blood obtained from a rapidly growing sarcoma and left in contact with the sarcoma cells on a slide does so also, although blood drawn from the finger of the same patient does not crystallise. In like manner a drop of blood flowing from a puncture made in granulation tissue does not crystallise, while blood on a slide containing the teased-up granulation cells does so readily. The same holds good for the spleen and liver. Now the question arises, How is this action on the red corpuscles brought about? Do the leucocytes, as they die and disintegrate, produce or liberate some ferment or chemical substance having this effect? Or do they simply act by depriving the hæmoglobin of the red corpuscles of its oxygen? And further, is the same influence exercised by damaged portions of any other tissues of the body as well as leucocytes and cell elements? The following observation may throw light here. The blood was examined from a calf's tail, and found not to crystallise. A ligature was then placed tightly around the lower end of the tail; the blood, thus rendered stagnant and in contact with the partially devitalised tissues, was examined at intervals of two and twelve hours and on the second day after, at which time the ligature was removed and necrosis had commenced; no crystallisation was detected except in one or two corpuscles on the second day. Also a drop of blood taken from tissues inflamed by mechanical means alone and unassociated with the presence of micro-organisms,

[1] This was written in 1886, before Dr. Copeman's article in THE LANCET of May 28th, 1887, on the Blood in Pernicious Anæmia.

Digitized by Google

as in eczema and burns of limited extent, does not crystallise, though this may be due to the fact that the individual corpuscles remain within the limited area of inflamed tissues for such a short time. Burns of large extent, in which there is a great reaction after the shocks, especially in fatal cases, generally produce a general crystalline change in the whole volume of blood, even although suppuration has not yet occurred; this result may, however, be due to great congestion and interference with the large internal organs. On the whole, then, we may conclude that spleen pulp, leucocytes, and tumour cells, when injured by withdrawal from the body, exert some influence on blood in contact with them, leading to crystallisation of the hæmoglobin of the red corpuscles. Further, where great numbers of these cells or tissue elements live, degenerate, and die in the body, they produce the same change in the blood circulating amongst them, and in some cases this influence may be so great as to affect the whole volume of the blood, as in the case of rapidly growing malignant disease. The more highly organised tissues, when injured, do not seem to exert the same influence either when in contact with blood on a slide outside the body or on blood circulating amongst them in the body. Extensive burns seem to be an exception, but we must in all these cases bear in mind the possibility of septic infection, which will of course produce the result.

As to the nature of this influence—whether, that is, these damaged leucocytes produce this crystallisation of the hæmoglobin by (1) the production or liberation by or from themselves of some chemical body or ferment, as in the case of coagulation; or (2) by depriving the red corpuscles of oxygen, or by both means combined, we do not yet know. As regards the manner of their action on a slide outside the body, it is interesting to note that the presence of mere organic foreign bodies, such as starch granules, in a drop of blood will not produce crystallisation, whereas the addition of some yeast fungus or torulæ brings about marked crystallisation; this fact suggests that the change in the blood is brought about by some action connected with the life of the leucocytes.

The Influence of the Death of the Body on the Blood.—Blood taken ten or twelve hours after death from the heart or large thoracic vessels of healthy persons who have died suddenly from accident almost always crystallises in about twenty-four hours; whereas blood taken from the vessels of the limbs crystallises but rarely, and then only after a long interval. Now we know that blood drawn during life and allowed to stand in a clean vessel does not crystallise even on a slide, at any rate in the case of man; and the difference in behaviour between the blood from the thorax and that from the limbs is probably due to the fact that the blood in the large cavities is kept warm for some hours after death, and within easy reach of the septic gas-containing hollow abdominal viscera. Moreover, the fluids in these cavities, thorax and abdomen, undergo a rapid change of some kind after death; for though normal pericardial fluid, when added to a drop of normal blood on a slide, produces no change, pericardial fluid taken from a healthy man twelve hours after death, and added to a drop of normal blood, produces marked crystallisation, although no organism can be detected in the fluid at the time. Further, the condition of the patient at the time of death also makes a great difference. Thus the blood of persons dying from wasting and febrile diseases, even though not crystallising during life, does so after death much more quickly and readily than the blood of healthy persons dying suddenly.

Crystallisation in Animals.—The tendency to crystallisation of the hæmoglobin in different animals of course varys greatly, not only in health and when treated by the many and well-known methods and reagents, but also in disease and when observed after the method explained above. Thus, in the mouse, wild and tame, at one end of the series, crystallisation readily occurs in the unaltered drop of blood on a slide, as explained above; in the field mouse it does so more slowly and less fully, also in the rat; and in the hedgehog, mole, guinea-pig, and rabbit it occurs with great difficulty when treated thus, though easily obtainable from these animals by treating the blood with reagents. In the dog there is no crystallisation in health; and in the cat there is slight crystallisation in a few corpuscles from the general circulation; it is, however, well marked in blood taken from the splenic vein during life, and less so in the hepatic vein; the animal, however, was dying from chloroform poisoning by inhalation; but this excess of crystallisation in the splenic vein points again to the influence of the spleen pulp on the red corpuscles circulating in it. The larger domestic animals seem to resemble man in the matter of crystallisation. Thus, in the sheep, though absent in health, I have detected the change in the blood of "rotten" sheep, also in cases of uterine inflammation after lambing, and in cases of the peculiar wasting affection found on cold undrained lands attended with destructive joint changes; on the other hand, it was absent in a lamb and sheep both dying suddenly from pericardial effusion or "red water." Although the crystals of hæmoglobin, appearing thus spontaneously, as it were, in the blood, belong in different animals, with few exceptions, to the same system, yet in these different species they present tendencies to assume for the most part one shape or size peculiar to that species or animal. Thus, in the sheep, in addition to the needles, the plates are generally of a diamond shape, unlike those of man. This points to a considerable difference in the intimate constitution of the hæmoglobin of various animals—a subject well worthy of further investigation. In the case of a wild mouse caught near Wimbledon in 1880, in which numerous actively moving flagellate organisms, probably identical with those described by Lewis as occurring in the rat, were found in the blood, very slight crystallisation was detected—less, in fact, than usual; thus giving another example, as was suggested in the case of anthrax, of an affection in which the parasite kills the host by the mechanical invasion of its fluids and tissues, rather than by the production or liberation of any chemical product. I have not detected any crystallisation in the nucleated corpuscles of toads, newts, or birds; in the fish, however (roach), it occurs readily, in health, in the form of needles and diamond plates. Thus, though animals differ in the tendency to crystallisation during health and in the unaltered blood, they resemble man in this respect, that in diseases of a septic nature and in others, and in the case, too, of blood to which septic serum has been added on a slide outside the body, crystallisation generally occurs.

What is the nature of this change shown by the hæmoglobin under these peculiar conditions? Whether we regard the blood according to the older views as an albuminous fluid only, in which float the corpuscular bodies, red and white, or whether we regard it in a new light suggested by Wooldridge and others, and consider it as a sort of embryonic tissue, an undifferentiated fluid protoplasm, in which the red corpuscles arise, or are born, as it were, by the differentiation and colouration of the little portions of protoplasm forming each corpuscle,—whichever view we take, we are here concerned only with the ultimate composition of the blood, and simply regard it as composed of an albuminous fluid portion or plasma, and a more solid or corpuscular portion, each corpuscle of which consists of a protoplasmic stroma containing in loose combination, or in some sort of physico-chemical association, a proteid-coloured body called hæmoglobin. This body is capable of existing in a crystalline and in a colloidal form, and in an oxidised and in a reduced condition, and it is now for us to attempt to explain the occurrence of the crystalline form in the blood of man in disease, since it only exists during health in the colloidal state. As regards the real nature of this change, we know that it is not due to a mere alteration of plasma or corpuscles due to high temperature, for it is absent in rheumatic fever. Neither is it owing to a disturbance of the relation between solid and fluid constituents, for it is not found in the blood of persons extremely anæmic from severe hæmorrhage. Neither is it simply a diminution in the volume or amount of the hæmoglobin, for it is absent in chlorosis. Now it happens that the result obtained by the disease—for instance, septicæmia—on the blood in the body can be produced by the addition to a drop of normal blood on a slide outside the body of some of the poison producing the disease. Thus, if a drop of putrefactive human serum be added to a drop of normal blood on a slide, well-marked crystallisation of the hæmoglobin occurs in twenty-four hours. And this holds good of other diseases, care being of course always taken to use only serum as the vehicle of the poison, so as to alter the composition of the blood as little as possible. In this way various agents can be used and the nature of the change more easily investigated. If a specimen of blood in which this change is going on be watched under a cover glass, it will be found that the first change, occurring in from six to eighteen hours, is nearly always an exudation more or less of the hæmoglobin into the serum; the corpuscles grow pale, while the serum assumes a yellowish tinge. A little later, in

Digitized by Google

from twelve to twenty-four hours, it will be found that crystallisation has occurred, and this chiefly in the red corpuscles, and, if the exudation of hæmoglobin has been marked, in the dissolved hæmoglobin also, around the margin, not, however, the extreme edge, of the cover glass. If normal blood be allowed to stand in quantity to which some hydrocele fluid which has been exposed to the air for some days is added, crystallisation does not occur to any extent in the blood standing in mass, but it appears as soon as a drop of such septicised blood is transferred to a slide and allowed to remain twenty-four hours; and if some of the same hydrocele fluid be added to a drop of fresh blood on a slide, crystallisation also occurs in twenty-four hours; whereas, fresh hydrocele fluid, free from organisms or their products, has no power to produce this change. From this it appears that the change brought about by the poison in the first instance, is an increased exudation of the hæmoglobin out of the corpuscles into the plasma, and then, when the conditions are favourable as to evaporation &c., as on a slide, crystallisation occurs in the exuded hæmoglobin and also in the corpuscles, the crystallisation being the second term in the series of changes. But this crystallisation is not merely an accident due to the exudation of the hæmoglobin and subsequent evaporation of the serum. This is proved by the fact that it is absent in the blood of typhoid fever patients, although in this disease there is considerable exudation of the hæmoglobin, and the conditions favouring evaporation are the same. And further, in many cases where the poison is highly concentrated, crystallisation occurs within the red corpuscles, before exudation of the hæmoglobin can occur. Thus the first effect of the poison in a moderate dose is to produce exudation of hæmoglobin, and, secondly, the conversion of this body from the colloid to the crystalline condition.

Now, bearing in mind that, though soluble in serum, the hæmoglobin does not leave the red corpuscles under normal conditions and in health, and since mere alteration of the density &c. of the serum alone has no power to bring about crystallisation, we are led to think that the action of the poison falls chiefly on the red corpuscles, and consists in a lowering of the vitality of the stroma, rendering it incapable of retaining the hæmoglobin in association with itself, just as, in order to prepare hæmoglobin artificially, it is necessary to detroy the stroma by reagents, or by repeated freezing and thawing. Further, this hæmoglobin, being itself a highly complex substance composed of a proteid body (globulin) and a coloured compound (hæmatin), is probably also affected itself; its vitality is also reduced, for it is converted from the semi-fluid colloidal state in which it exists in association with the stroma into the rigid, less vitalised, crystallised state. But this is not all. If a drop of normal blood be watched on a slide for some days, it will, on examination with the micro-spectroscope, always show the two narrow bands characteristic of oxyhæmoglobin; it becomes—remains, in fact, in an oxygenated or arterial condition, even though venous or deoxidised when first drawn. On the other hand, in poisoned or crystallisable blood, one of the first changes after the exudation of the hæmoglobin is that, no matter in what state it was first placed on the slide, it invariably shows the one broad band characteristic of reduced hæmoglobin; it becomes, in fact, very venous in proportion as the exudation and crystalline changes progress. This reduced spectrum is not obtained at first alike all over the field, but occurs first in patches where the exudation and crystallisation are setting in—not, however, just round the extreme margin of the cover glass, for here, just inside the dried blood, which forms a protecting scab, is a zone of highly oxygenated blood, in which neither exudation nor crystallisation ever takes place. The crystalline and venous changes occur in a wide zone just inside this oxygenated zone, and this relation of zones is, no doubt, determined by the physical conditions of exposure, evaporation, &c., the important point being, that these changes do not occur in blood which is not diseased, or has not been treated with septic serum in the way described. Further, although the crystals of hæmoglobin, when obtained by the usual methods, are capable of existing in the oxidised or in the reduced condition, yet when occurring in such poisoned blood, they are, like the blood, always in the reduced or venous state; this is shown both by their purple colour and by the micro-spectroscope.

Now, this fact—namely, that the hæmoglobin of patients suffering from these diseases, septic and others, in which crystallisation occurs when placed on a slide, always loses its oxygen, whereas the hæmoglobin of normal blood, when so treated, always gains or retains its oxygen, no matter in what state it is when drawn—is very important. Such hæmoglobin has not lost the power to take up oxygen, for when exposed to the air the blood again becomes arterial, but when confined under the cover glass and the air excluded by the dried scab, it in some manner has the oxygen removed from it. Now the question is, What is the agent by which this loss of oxygen is brought about? Mere organic foreign bodies, such as starch granules, do not produce either exudation, crystallisation, or reduction of the hæmoglobin. If, on the other hand, some living torulæ cerevisiæ be added, then deoxidation occurs in addition to the exudation and crystallisation described above. Torulæ differ from starch granules, especially in these particulars—that they are alive, that they are associated under certain conditions with fermentative changes, and that they require and abstract oxygen from the surrounding media. Moreover, we have seen before that the contact of leucocytes or sarcoma cells with the blood under like conditions will bring about this exudation, crystallisation, and deoxidation, and there is evidence to show that leucocytes and bodies resembling them, in addition to requiring oxygen, are associated, when injured or undergoing disintegration, with some ferment-like bodies, having important effects on the blood as regards its tendency to crystallisation.

Judging, then, from the foregoing facts, I may state that the blood in the septic and infective diseases mentioned above, also when associated with the presence of large quantities of leucocytes or sarcoma cells and cell elements of a like nature, or when treated outside the body by the addition of septic serum, undergoes certain changes in which the hæmoglobin especially suffers—passing through a triple retrogressive change of exudation into the serum, deoxidisation, and crystallisation. Though, of course, it is extremely difficult to separate and distinguish between effects due to the mere presence of the micro-organisms and those due to the products of the growth, yet we know that in some affections, at any rate such as sapræmia, the change in the hæmoglobin is associated with the presence in the blood of certain chemical products, the micro-organisms themselves not getting into the circulation. From these and other facts we are led to believe that it is the chemical albuminous ferment-like bodies which are produced by the growth of the organisms in the one case, and the products of the disintegration of the devitalised leucocytes or tumour cells in the other, which brings about these changes in the hæmoglobin, and not the mere presence of the organisms or leucocytes themselves.

I am fully aware that there are many cases in which a further examination of the blood may throw important light. Thus it would be especially interesting to note the presence or absence of this change in the case of poisoning by snake bite, the poison of which has now been more fully worked out; also the injection of the isolated products—such as sepsin &c.—themselves into the circulation would give additional evidence; also the injection of bodies of an analogous nature—such as the ferments, pepsin, trypsin, &c. For these and other experiments, further opportunities may arise.

In conclusion, I venture to think that the results obtained and stated in the foregoing pages explain certain phenomena which have hitherto existed as isolated facts. It has been known for some time that the actual quantity of oxygen in the arterial blood of animals suffering from septic diseases is diminished; this is now explained by the deoxidising action of the poison on the hæmoglobin. It is also of course frequently observed that considerable post-mortem blood staining of the endocardium and interior of the large vessels occurs in the bodies of patients dying from septic diseases. We have seen above how the action of the poison of these diseases is to cause exudation of the hæmoglobin from the red corpuscles into the serum, and so to bring it in contact with the tissues.

DRAINAGE OF THE CITY.—At a meeting of the City Commission of Sewers on Tuesday, the Streets Committee were charged with the duty of considering whether any, and, if any, what better method could be adopted for cleansing the catchpits, gullies, and drains in the City and for improving the construction of the drain pipes leading to the main sewers.

CYSTOTOMY IN ADVANCED VESICAL CANCER.

BY T. D. COLLIS BARRY,
SURGEON, BOMBAY MEDICAL SERVICE.

THE following three cases are practical illustrations of the advantage to be derived from cystotomy with perineal drainage in cases of advanced cancerous growths of the bladder.

CASE 1.—F. W——, aged forty-three, engineer, had been suffering for five months from severe pain in the lower part of the back, dragging pains in the groin and perineum, accompanied latterly by hæmaturia and intense flashing pain during and after micturition, described by the patient as commencing in the perineum and extending along the urethra to its termination. The patient had been under treatment at a hospital, and his case diagnosed as cancer of the bladder. Upon examination with a No. 8 sound, the latter met with an obstruction just behind the prostate gland, and with the finger in the rectum a growth upon the base of the bladder in this situation was distinctly perceptible, and there was little doubt that it was of a cancerous character. The examination of the urine and deposits microscopically gave no distinctive indications. The pain became so intense, and the repeated desire for micturition so constant, that the patient's life became a misery to him. The association of the flashing pain with each act of micturition suggested the advisability of opening the bladder from the perineum, and inserting a tube after the manner usually adopted in cystotomy. After operation half a grain of morphia was administered hypodermically to allay pain and induce sleep. The following morning the temperature had risen to 101°, but fell to normal during the day. There was no pain accompanying the emptying of the bladder, the urine passing away by the perineal opening freely. There was a little cystitis, which was got rid of by washing out with hot boracic acid solution. The temperature remained normal from the second day after operation, and the pain formerly complained of had disappeared entirely. The patient was up in ten days from the date of the operation, and for seven months was able to get out of doors without any more inconvenience than that caused by the presence of the perineal tube. Shortly after this (nine months after cystotomy) his strength began to fail, and he died after a few days' confinement to bed.

CASE 2.—J. S——, aged forty-six, sailor, lately returned from Northern India. He had been under treatment for cancer of the bladder in the Calcutta Hospital, but had left there in order to rejoin his ship. The symptoms were much the same as in the preceding case, but there was more loss of flesh and more cachexia. The use of the sound gave little evidence beyond proving the existence of a small sacculation behind the prostate gland. There was enlargement of the inguinal glands on both sides, and the same flashing pain preceded and accompanied micturition as in Case 1. Cystotomy was performed, and after a somewhat tedious recovery he began to regain his strength, and the pain formerly accompanying micturition entirely ceased. He was able to walk out for a short distance every day, and he passed the remaining nine months of his life in comparative comfort, death eventually occurring through a fall from a vehicle.

CASE 3.—A. B——, aged sixty, engineer, had been under treatment for cancer of the bladder for three months. When he first came under my care he was suffering from intense pain preceding micturition, and there was enlargement of the right inguinal glands. Cystotomy was resorted to, and within three weeks the patient was able to get about with the help of a stick. For three months he was able to go out of doors morning and afternoon, with his perineal tube attached to an indiarubber urinal. The pain formerly accompanying micturition, though not entirely ceasing, was, nevertheless, so slight as to cause him little or no inconvenience until three months after operation, when the cachexia suddenly and rapidly increased, and he died after a few days' illness.

Remarks.—It will be observed that in all three cases recorded the disease was advanced and the flashing pain accompanying micturition the most prominent symptom, and it was with a view to relieve this distressing symptom that the operation was in each case performed. The relief afforded by the perineal drainage in these cases is unmistakable, and the shock following the operation is so slight that it need hardly be taken into account even in the most debilitated. The operation is certainly justifiable in all cases where there is much pain, and holds out a very fair prospect of relief during the remaining months of life. It is found convenient to have the perineal tube fitted with a silver tap, which the patient can use when he desires to empty the bladder, otherwise he must have the tube connected by means of a rubber tube with a portable urinal.

Netley.

CASE OF ANOMALOUS NERVE DISEASE,

WITH NECROPSY AND EXAMINATION OF CORD.

BY JAMES MATTHEW CAW, M.B.,
WOOLWICH UNION INFIRMARY.

IDA A——, aged fourteen, domestic servant, was admitted to the Woolwich Infirmary on Nov. 4th, 1886. Previous to her removal from her home it was found necessary to administer chloroform, on account of the suffering experienced on movement and touch of the lower extremities. She complained of inability to move the lower limbs, which were drawn up in the flexed position; of excruciating attacks of pain in the lower part of the spine and sacral region; and of intense pain of the legs, from the sacrum and iliac crests downwards, when touched or on attempting to move them. She had always enjoyed good health until her present illness. There was no history of any inherited taint, her mother, brother, and sister being apparently quite healthy. Nine weeks before admission her mother gave her a dose of "pennyroyal," thinking to aid the menstrual flux, which she thought was somewhat delayed (the girl had been "unwell" for the first time about a month previously). Next morning, while sitting at breakfast, she was seized with a feeling of cramp in her legs, and sensations as of "pins and needles." On rising to go to her work (that of a day servant) she fell, but was able to reach her destination, though with some difficulty. The feeling described lasted throughout the day, and she had to be conveyed home in the evening. Then, for the first time, while sitting on a chair, she was attacked by an excruciating pain in the lower part of the spine, which she described as being "like knives digging and scraping." During the night she had several of these attacks, which compelled her to lie on her side with her legs drawn up. Never since the first seizure had she been able to move her legs without severe pain. The numbness gave way to intense sensibility of the skin of the lower limbs, which became rigid and fixed in the flexed position (legs on thighs and thighs on abdomen). Attacks of pain, as described, occurred two or three times every day. A bedsore on each hip had developed, and several ulcerous patches over the lower limbs. She had had no return of menstruation since the commencement of her illness.

On admission the patient was observed to be an intelligent girl with a pained expression of face. Her lower limbs were drawn up as described. She began to cry when she thought she was to be touched. The upper limbs and trunk were unaffected. There was intense hyperæsthesia of the lower limbs. The latter were covered with ulcerating patches, which seemed to greatly undermine the skin. On each tarsus were one or two perforating ulcers, leading down to carious bone. Over each hip was a large bedsore, exposing the capsule of the joint. The vulva and parts surrounding were covered with an eczematous rash, due in all probability to neglect of cleanliness. There were several blebs containing a dark-coloured serum over the legs, varying in size from a sixpenny-piece to half-a-crown; these on bursting were found to leave ulcerating patches, the larger having little or no tendency to heal. Her appetite was good; defecation was attended with severe pain of a lancinating character, and micturition was easy and apparently normal.

The patient continued in much the same state for three months after admission; ulcers forming, healing up, and re-forming; excruciating attacks of pain coming on about twice a day; the bedsores on hips increasing, and extending underneath the skin to the vulva, which began to slough, attended by considerable bleeding. The disease did not extend up the trunk, or involve the arms. She gradually sank from exhaustion and hæmorrhage, intelligence remaining pretty clear till the last. No treatment seemed of avail.

Digitized by Google

Iodide of potassium, nitrate of silver, &c., did not seem to have any effect on the lancinating pain. The sores were treated with powdered iodoform applied on wool. The diagnosis which appeared most probable was that of hæmorrhage into the cord, followed by myelitis and softening. This seemed the more likely as the onset of the disease occurred at the time when the second menstrual period was expected, and possibly a vicarious hæmorrhage might have taken place into the spinal cord.

At the necropsy the lower extremities were observed to be much swollen, and presenting the appearances already described. The uterus and abdominal organs were healthy. On removing the spinal cord no hæmorrhage, meningitis, or patch of softening was observed. Having hardened the spinal cord for three weeks in bichromate solution, I examined it under various powers of the microscope. Only in the region of the lumbar enlargement was anything abnormal detected. Of many sections from this part of the cord which I examined, nearly all showed signs of absorption or softening of that part of the grey matter situated near the junction of the grey commissure with the grey matter—that is, in the neighbourhood of Clarke's posterior vesicular column. At the necropsy the sodden, rotten state of the skin was particularly noticeable, being hardly capable of retaining the stitches which were inserted on sewing up the body.

The case seems to have been one of acute degeneration of the grey matter, most probably involving the tract containing the trophic nerves of the skin, which are said to pass along the middle of the grey matter. The intense hyperæsthesia distinguishes it from acute anterior poliomyelitis, although it is most probable that the anterior cells of the grey matter were also considerably involved.

ANALYSIS OF THE URINE IN TWO CASES OF CEREBRAL ABSCESS.

BY W. F. SOMERVILLE, M.A., B.Sc., M.D.,
ASSISTANT SURGEON TO THE GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR.

Two cases of abscess of the brain have recently occurred in the Glasgow Ear Hospital, under the care of Dr. Thomas Barr. I had the opportunity of examining the urines of these patients, and the results obtained appeared to me to illustrate well the great advantage, as an aid to clinical diagnosis, of the complete examination of the urine. The analysis was conducted in accordance with the method originated by Mr. A. E. Haswell, pathological chemist to the St. Joseph's Children's Hospital, Vienna.

In all, six specimens of urine were examined: two from a girl aged twenty (K. A——), who died, the diagnosis being confirmed by post-mortem examination; and four from a boy aged nine (W. H——), who recovered after evacuation of the abscess by Dr. Macewen. These specimens naturally fall into two groups: in one are the urines of the girl who died, and of the boy before operation; whilst included in the other group are the specimens of the urine passed by the boy subsequent to operation. A comparison of these two groups will illustrate certain striking differences between the urines excreted when pus was present in the brain and those after its removal.

GROUP A.—The following characters common to these three specimens are to be observed:—

1. In each there are distinct evidences of the existence of a *status febrilis*. These are most conspicuous in Nos. 2 and 3. Taking the latter as an example, we observe that the quantity of urine passed in twenty-four hours is small—0·41 litre,[1]—the specific gravity excessive, the reaction acid, and the colour high; that the elimination of urea, even during temporary starvation, is relatively abundant; and that the amount of extractive material—principally pigments—is increased. All these facts tend to demonstrate the presence in the body of a *status febrilis*. This is the more worthy of attention, since the thermometer did not reveal any decided elevation of temperature, though it is clear from what is stated above that the metamorphosis of tissue must have been proceeding with abnormally excessive activity.

[1] Of course, it must be borne in mind that the quantity of fluid imbibed by the patient at this period was small, he lying in a comatose condition. No fluid, however, was lost by vomiting.

2. A great diminution in the amount of chlorides relatively to the total dry residue is noticeable. Thus in urine No. 3 the dry residue is 74 per mille, and the proportion of chlorides in that amount of dry residue should be 11·1, whereas it is only 4·1. A similar disparity exists in urines Nos. 1 and 2.

3. There is a decided increase in the amount of phosphates excreted relatively to the dry residue. For example, in urine No. 3 the amount eliminated was 9·1 per mille, when with a dry residue of 74·5 per mille it should have been 5·5. The same feature is seen in urine No. 2, and to a less extent in urine No. 1, which was passed a month before death, when it may be presumed that the cerebral mischief was but limited. It is to be remarked that this increase in the total amount of phosphates includes an increase of earthy phosphates. This is very prominent in No 1, and less so in No. 2, whilst in No. 3 the increase of earthy phosphates is but fractional. But it must be observed that urines Nos. 2 and 3 indicate the existence of more active febrile processes, and accompanying such processes we should expect to find a diminution of earthy phosphates. The fact that these salts in No. 2 are not diminished, and in No. 3 approximate to the normal standard, must be regarded as equivalent to an actual increased elimination.

GROUP B.—The characters which attracted attention in the urines of Group A may now be compared point by point with the corresponding features of the urines of Group B.

1. From the analysis of the urines of Group A several facts emerged indicating the existence of excessive tissue changes. These features were most marked in urine No. 3. Now, when attention is directed to the corresponding points in the urines of Group B, it is at once seen that a conspicuous difference exists. Further, it will be observed that the improvement in these respects is progressive. The facts as regards quantity and specific gravity are as follows:—In urine No. 4 only 0·28 litre is passed in twenty-four hours, and the specific gravity is 1030. It will be noticed, therefore, that the quantity passed in twenty-four hours shortly after, is less than that passed during the twenty-fours preceding operation; but whilst this is the case, the specific gravity has fallen from 1032 to 1030. At the same time the reaction has become less strongly acid, and the colour of the urine is lighter. In other respects the urines resemble one another, so that we conclude from urine No. 4 that undue tissue change is proceeding (i.e., after operation), though this is not so extreme as before operation. (See urine No. 3.) In urine No. 5, seven days after operation, the quantity of fluid has considerably increased—viz., to 1·28 litre,—whilst the specific gravity has fallen to 1009·5. Urine No. 6, thirteen days after operation, measures 1·31 litre in twenty-four hours, and the urinometer indicates a density of 1012. The marked and progressive improvement is here conspicuous. Further, these two specimens do not illustrate in their other features the presence of a *status febrilis*. The reaction in the one is alkaline, in the other neutral. Each is of a pale amber colour. There is no marked proportionate excess of urea, and though the amount of extractive material is still abnormally large when compared with the total dry residue, the above facts show that some explanation of this, other than excessive tissue change, must be sought for.

2. The change in the elimination of chlorides is significant. In urine No. 4 the chlorides, though still far below the amount which ought to be present in a dry residue of 69·9 per mille—i.e., 10·3,—are not so deficient as in urine No. 3. The dry residue in urine No. 5 is 22·1 per mille, and the normal proportion of chlorides in this is 3·3 per mille; the actual proportion present is 2·4 per mille. Whilst No. 6, with a dry residue of 27·9 per mille (normal proportion of chlorides 4·1 per mille), yields 4·7 of chlorides.

3 There is seen to be a progressive diminution of the phosphates, which ultimately reach the normal standard. Thus in urine No. 4 the normal proportion of phosphates relatively to the dry residue is 5·2 per mille, whereas they were found to be 6·2 per mille. In No. 5 the normal proportion is 1·6; the proportion present is 1·79. Whilst in No. 6 the amount of phosphates present bears to the dry residue a normal relation. The earthy phosphates in the three urines are observed to be either approximately normal or subnormal; whereas in the urines of Group A—i.e., whilst pus was forming in the brain—these salts were found in excess.

It is impossible within the limits of this paper to state fully the diagnostic value of these facts. Many of them

have considerable negative significance, and would at once enable the physician to limit the possible diagnoses. The positive conclusions to which the analyses in Group A point are three in number: 1. That a *status febrilis* exists. 2. That this is accompanied by inflammatory exudation (diminution of chlorides). 3. That great destruction of nervous tissue is going on (increase of phosphates). Moreover, the high colour and excessive specific gravity of the urine, with the amount of earthy phosphates eliminated, indicate that this destruction is occurring in the nervous tissue of the brain. The analyses under Group B emphasise the significance of the facts to which special attention has been directed, and the assistance to be derived from such knowledge exemplifies the value as an aid to clinical diagnosis of a complete examination of the urine.

CASE OF

PLASTIC OPERATION FOR DESTRUCTION OF NOSE BY SYPHILIS.

BY C. M. CAMPBELL, M.D.

W. W——, an undersized boy, aged fifteen. Parents alive and healthy; five brothers and sisters alive and healthy; one brother died, aged fourteen months. When aged seven he suffered for two years from his eyes (keratitis?), and at nine from a general skin eruption, consisting of red, dry, scaly patches. This lasted an uncertain period, and was followed by hard glandular swellings in the neck, which remained several years. When aged thirteen he began to snuffle, the nose became swollen and tender, and he lost flesh rapidly. At this time (exact date uncertain) the bridge of the nose was lacerated by a stone, and the wound remained an open sore. He was treated for this condition in

FIG. 1.

a provincial hospital, where it was diagnosed as lupus; but in spite of every care the disease advanced. In January, 1887, perforation took place, the nasal bones exfoliated, and the patient became alarmingly weak. He was admitted into St. John's Hospital for Skin Diseases on Feb. 24th, presenting the following conditions: Great prostration, feeble pulse, anorexia, and insomnia. The nose, except the tip and alæ, had disappeared, and in its place was an irregularly-shaped aperture, an inch and a quarter by three-quarters of an inch, with ulcerating edges, opening into the nares. Discharge profuse and foul; septum gone. (See Fig. 1.) The tip and alæ were of a dusky purple colour, as if about to slough. The free edge of the soft palate ulcerating, and deeply cleft by a ragged fissure to the right of the uvula, which hung by a thin shred of tissue. Tonsils and pharynx swollen, red, and showing several shallow ulcers. Teeth irregular and ridged, but did not exhibit Hutchinson's notches well marked. Treatment: Full diet, with claret; pulv. hydr. c. creta, gr. iii., om. noc.; mist. sodii iodi. (gr. xv. of the salt) ter dies sum.; nasal cavity repeatedly syringed with sol. hydr. perchlor., 1 in 1000, and insufflated with iodoform. The case at once began to improve, and after five weeks the edges of the nasal wound had healed; the tip and alæ became normal in colour, but much contracted, so that the single nostril (the septum being gone) scarcely admitted the tip of the little finger. The nasal wound now measured one

FIG. 2.

inch by half-an-inch; the faucial and palatal ulcerations had healed, and the general condition greatly improved. Mist. sodii iodi continued; hydr. c. cretâ stopped. The face being hideously disfigured (see Fig. 2) and phonation interfered with, I resolved to make an attempt to close the aperture, but judged that it would be unwise, in the doubtful

FIG. 3.

condition of the patient's tissues, to do more than this in the way of making a new nose.

On April 20th, under chloroform, the nostril was fully dilated, and the upper free border of the tip and alæ vivified. Incisions were made along the outer borders of the alæ, and carried outwards and then upwards towards each eye. The edges of the nasal aperture were then vivified, and the flaps dissected upwards until sufficiently free to meet in the mesial line without tension. About an inch and a half of stout rubber tubing was passed up the nostril, keeping it dilated, and over the tube the flaps were adjusted and secured to the tip, alæ, and to each other in the mesial line, by harelip pins and silver sutures. The cheeks on each side were drawn towards the nose by strips of salicylic plaster, and the surface dusted with iodoform, and covered with cotton wool. The needles and sutures were removed on the fourth day. The flaps had then joined, except for about one-fifth of an inch in the mesial line near the tip. This, however, granulated and closed, without any aperture, in a few days. On April 28th the iodide of sodium was stopped, and syrup of hypophosphites (one drachm, three

Digitized by Google

times a day) prescribed. On May 5th the wound had healed, and the patient appeared as in Fig. 3. Phonation had greatly improved. The patient was discharged, with directions to continue dilatation of the nostril, which showed a tendency to contract.

Remarks.—There was no clear history of syphilis on the parental side, and the case was sent to St. John's Hospital as one of lupus. The absence of lupus on the face, and the limitation of the rapidly destructive processes to the nose and naso-pharynx, rendered such a diagnosis inadmissible. The good effect of iodide of sodium in full doses (forty-five grains a day) was well illustrated in this case. Whether the syphilis was inherited, or acquired accidentally in childhood, I am unable to decide.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

WHAT IS THE AVERAGE LAPSE OF TIME BEFORE THE RETURN OF CANCEROUS DISEASE AFTER OPERATION?

By FRED. A. A. SMITH, M.D.

WE all know how difficult it is to get patients the subjects of cancer to submit to an operation before the disease has made such progress that life becomes unbearable. Then, and not till then, will they submit to an operation which for obvious reasons is too often only palliative, with the consequence of an early return of the disease and death. My reason for writing these few lines is to show in a small way how great the boon might become would patients only submit to early operation. Even should the tumour be found after excision to be innocent, a constant source of mental discomfort is clearly removed, and tumours of all descriptions are unsightly and troublesome. The subjoined case was operated upon by me in 1868, and until a few weeks ago the lady has had no return of the disease, when she observed two small tumours in the cicatrix of the former operation, with constant pain.

In 1868 a lady, aged forty-one, consulted me about a painful tumour in her right breast. It was the size of a large walnut, smooth, and movable in all directions. She was advised to submit to an early operation, and after a few weeks' consideration consented, the consequence being that for nearly nineteen years no return of the disease took place. After excision, well-marked cancer cells were observed under the microscope. I should like to know whether many such cases have been observed, and whether an early excision of the secondary growth is not equally advisable, because the lady does not wish to have the tumours removed. At present they are small, smooth, and movable, but may rapidly enlarge at any time.

A READY METHOD OF REMOVING FOREIGN BODIES FROM THE ANTERIOR NARES.

By T. OSBORNE-WALKER, M.R.C.S.

I HAVE many times been called upon to remove peas, buttons, and various substances from the nostrils of children, who have themselves introduced them there. The last case occurred to a little boy, whom his mother brought to my surgery on Aug. 1st with a boot-button tightly impacted in the angle between the vomer and os nasi at the bridge in the right nostril. Ineffectual attempts at extraction had evidently been made, as shown by blood oozing from the nostril, and some, coagulated, adherent to the button, partially concealing its outlines from view, and also by the button being fixedly jammed in. As is my practice in such cases, I first confined, to prevent struggles and interruption, the child's arms, hands, and legs, by folding tightly round these and the body a long, clean white apron, which the mother was wearing, and then, placing the child on his mother's lap, facing a window, while I stood behind the patient, and, bending over and depressing with two fingers of my left hand the apex of the nose, to admit as much light as possible upon the object to be removed, I introduced with my right hand very carefully, to avoid its descent into the pharynx or larynx, the spoon end (with the concavity directed forward) of an ordinary pocket-case director, with which I ejected at once the button with a simple lever movement or jerk.

By attention to the following points the removal is instantaneously effected: The close confinement of the hands, arms, and legs by a shawl, blanket, or apron; a good light; a reliable person to securely hold the child; the position of the operator behind the patient; depressing well the apex of the nose to obtain a good view of the object; and lastly, getting the concave face of the spoon of a director fairly behind the body before making the forward lever movement.

IMPERFORATE ANUS.

By JAMES DALGLEISH, M.B., C.M. EDIN.

THE following case is, I think, worthy of consideration as showing how much may be left to nature in the repair or growth of the tissues in very early infantile life.

My attention was called to the fact that an infant, otherwise quite healthy, at the fourth day of its life had not had any motion of the bowels. On examination I found the anus apparently normal. The appearance was, however, deceitful, as on entering my digit I discovered that it terminated in a *cul de sac* about an inch deep. I pierced the mucous membrane forming its floor, through an ear-speculum, with a tenotomy knife, but was disappointed to find that no meconium appeared, and that evidently there was more abnormal than the septum of mucous membrane I had expected. The child was being well nourished and showing little sign of discomfort. The next day I operated. Without enlarging the natural external aperture, which was dilatable enough to admit my forefinger, I found by cutting through an amount of cellular tissue, which occupied the place of the rectum, that the bowel terminated as high up as my finger could just reach with an effort—i.e., about three and a half inches. With my finger, carbolised, I broke down a clear passage to this point, and, pushing my knife on the flat along my finger, I freely incised an opening in the gut, when there was a most plentiful flow of meconium, and presently the ordinary fæcal discharge. Beyond instructions towards the greatest possible cleanliness, I took no more pains in the case, and now, two months later, there has evidently been a downward growth of the mucous membrane to form a rectum. The child has regular motions, and, as far as the *primæ viæ* are concerned, has never shown a bad symptom. The reservation I make simply refers to an attack of bronchitis from which it has since suffered.

Trowbridge, Wilts.

CASE OF SUPERFŒTATION.

By GEORGE GILES, L.S.A.

As there has been a great diversity of opinion upon the possibility and probability of the above subject, the following facts may be of interest.

On Aug. 6th, 1887, Mrs. H——, who had gone to visit her mother in Holbeck, was suddenly taken in labour, and Dr. Mann (Messrs. Mann and Woodcock) attended, and delivered her of a fœtus at half-term about 8 P.M. Being compelled to go to another case about 11 P.M., Dr. Mann requested me to call and see if it was not a case of twins. I did so, and on external manipulation found another fœtus, and which I got away alive (the first being dead), about fourteen inches long, weight about four pounds, and which appeared about seven months and a half old, although very livid. This child lived from two to three hours. The placentæ were quite distinct (the second placenta being of a large size). The liquor amnii was also separate. It is quite evident that when gestation had progressed from two and a half to three months, in the case of the elder fœtus, that a secondary conception undoubtedly took place, the second ovum becoming developed independently of the first. I have preserved the first fœtus, the second having been interred before I called again. The question of bifid uterus I did not ascertain, but up to the present the woman is doing well. Playfair says it is probable; Galabin does not make any note of it.

NORTH LONDON HOSPITAL FOR CONSUMPTION.

EMPYEMA OF FOUR YEARS' DURATION TREATED BY INCISION AND DRAINAGE; MELANCHOLIA; REMARKS.

(Under the care of Dr. SQUIRE.)

THE treatment of empyema by incision and drainage in cases where it seems hardly probable that any good can be done in other ways, because of disease in other parts and the feebleness of the patient, receives encouragement from the record of the following case. Four years is a long time for the disease to exist in these days when the treatment is fully recognised, and cases seldom present themselves for help at so late a stage. Extreme emaciation and feebleness, some hectic, wearing cough with profuse expectoration, with signs of disease in the lungs, and albuminuria made the man's condition most serious. The onset of melancholia when otherwise the patient was progressing satisfactorily is interesting. For the notes of the case we are indebted to Mr. P. Moriarty O'Brien, resident medical officer.

G. S—— was admitted on Feb. 3rd, 1887, in a very weak condition. Family history good. The patient was strong, and had always been healthy till four years previously. He then had a rigor; no symptoms followed, and he was able to resume his work next day, and continued working for two months, when he again had a rigor, this time very severe in character. He was then compelled to give up work, as he felt very ill. Cough, with free muco-purulent expectoration, vomiting, dyspnœa, loss of appetite, sweats, and great thirst were present, but there was no pain to speak of. He was then admitted into Whitchurch Infirmary, where he remained nine months. During this time he improved, his breathing became better, and towards the end of the time he began to gain flesh, and to be able to walk short distances. On leaving the infirmary, he went to Andover Union, where he remained between four and five months, his condition remaining about the same. Since leaving the union he had been at home, gradually losing flesh and strength, and had been bedridden for the last two years. During the first seven months of this time, the expectoration increased in quantity. An abscess then formed in the right side, which broke and discharged a quantity of offensive pus. Three sinuses formed (two of which had healed during the last two months). Following this discharge of pus, the expectoration diminished in quantity, but remains considerable even to the present time—upwards of a pint in twenty-fours; this, however, is steadily diminishing. For some months the discharge from the sinus remained very profuse, but gradually lessened, and is now less than an ounce in twenty-four hours.

Present state.—The patient is a medium-sized, fair-complexioned man. He has the appearance of having been very strongly built, but now appears very weak, and is unable to stand without assistance. His face has a pasty appearance, very unhealthy and pallid. The skin is hot and clammy; no lividity or duskiness. The finger and toe ends are clubbed. No œdema now present or recollected. Decubitus almost entirely right-sided; rarely dorsal; never left-sided. Tongue clean, moist, and fairly healthy in appearance; appetite good; bowels regular; no diarrhœa; no sickness except sometimes on coughing. There has never been any hæmoptysis, but the phlegm has occasionally presented streaks of blood. Night sweats slight, and occasional sweating of hands and feet, profuse at beginning of illness. The cough is not very troublesome; it comes in fits, and is accompanied by retching. The expectoration is profuse and muco-purulent (it amounts to upwards of a pint in twenty-four hours); during the fits of retching half a pint is brought up. There is no distress, pain, or dyspnœa (formerly a marked symptom), and he speaks without effort. Specific gravity of urine 1024; slight amount of albumen, also slight mucous deposit. Pulse 96, regular, sustained tension, and firm. Temperature in the morning, 98°; evening, 101°. The following are the physical signs: On inspection the remains of a large chest are found, the bones being large and spaces wide; the coverings are much wasted. On the right side there is marked bulging in the lower mammary region from the fourth to the seventh rib, and laterally from the right border of the sternum to the anterior axillary line, but the whole right side appears fuller than the left. On deep inspiration the right upper front above the nipples appears motionless, and is much flattened; the same region on the left moves well. Clavicular hollows not marked. The sinus above mentioned is situated in the fifth space in the anterior axillary line, two inches and a half below and an inch and a half posterior to the nipple line. The inferior costal spaces on this side are difficult to define, the tissues appearing matted together. No fluctuation to be made out; no mapping out of the superficial veins, except about the shoulders, and here only slightly. Left mammary region below the nipple flatter than normal. Palpation shows absent vocal fremitus below the nipple on the right side; slight above this, and fairly good in scapular regions; good all over the left side. On percussion an impaired resonance is found over the front of the left apex, extending to the second rib; there is dulness in the supra-scapular region, but good note elsewhere. On the right side dulness, differing in degree and character, is found all over the lung. Good resonance is found in the mid-sternum, but less of resonance in other regions; high-pitched to the third rib and in the supra-scapular fossa. From this level to the fifth rib level, and over an area oval in shape, measuring five inches by four, the long diameter reaching to beyond one inch in the nipple line, there is a note, hollow in character; in the axilla there is absolute dulness. Posteriorly the mid-scapular dulness is less wooden in character than over the back generally. Auscultation shows over the left side coarse respiration. Inspiratory murmur exaggerated all over; more harsh in character over the apex, where bronchophony is heard; there is undue conduction of heart sounds all over the front. On the right side, practically nothing audible, respiratory or adventitious, beyond very faint entry of air at the extreme apex in front. Suspicion of scraping friction sounds over the mammary region; no ægophony, or any approach to it. Cardiac dulness commences at the upper border of the third rib, and extends on the left side as far as the nipple line. Impulse is seen in the third and fourth spaces; the maximum intensity is felt in the fourth space in the nipple line. Friction sound heard in the second and third spaces, on the left side occasionally double. Very faint sawing bruit localised at apex; sounds are ringing.

Feb. 16th.—The patient's condition has remained much the same as on admission. He has vomited once in twenty-four hours; during a fit of coughing, bringing up about half a pint of muco-purulent material. The opening in the right axillary line was enlarged by Mr. Godlee to-day, two small portions of rib removed, and a drainage tube inserted. Chloroform was the anæsthetic used. During its administration blueness of the face, pallor, and coldness of the extremities, with much troublesome cough, were noted. Forty ounces of fetid pus came away through the incision. The probe showed a large cavity extending almost to the apex; the ribs were very much approximated, extremely soft, and spongy. The wound was dusted with iodoform, dressed with boracic lint, over this being placed a pad of tenax, and then the bandage. The wound was dressed again in the evening, the discharge being profuse, coffee-coloured, and offensive.

17th.—Wound dressed this morning; discharge same as last evening. Much nausea existed after the chloroform, which was relieved by sucking ice.

19th.—From this date onwards the cough and expectoration ceased, the temperature not rising above 98·4°, and the general condition improving. The area mentioned above—viz., third to fifth rib—in which the note was high pitched, has extended into the axilla and upwards towards the apex. Some crackling sounds heard over the cardiac area; no bruit. Discharge changed gradually to a chocolate-coloured, thick, offensive pus.

March 2nd.—Felt faint twice to-day; pulse 104, full and feeble. Drainage not sufficient, so that it was necessary to turn the patient on his side to empty the cavity. Amount

Digitized by Google

diminished; still offensive. Harsh tracheal breath sounds now heard over inner half of infra-clavicular region; elsewhere no sounds to be heard; here and there echo and bell sounds on percussion of coins; on the left side the crackling sounds heard over the cardiac area have extended.

7th.—Wound dressed daily. Discharge lessening; reduced to two ounces to-day; not offensive now. The tube, which at first caused distress through pressure on the diaphragm, which ascended after the evacuation of the pus, was shortened, and now causes no pain. The patient is still faint on assuming the sitting posture. Cavity contracting to a sinus, and external opening showing great tendency to close.

20th.—Discharge now reduced to less than one ounce. Cavity much contracted. Tubular respiration extending a good deal over the chest. For the last few days the patient has been very troublesome, desiring to leave the hospital. Has suffered from melancholia during the last four or five days, and last evening, taking advantage of the relaxation of watchfulness on the part of an attendant, obtained possession of a knife and inflicted a wound on his throat. The wound was cross-shaped and jagged, but superficial. There was a good deal of venous hæmorrhage; this ceased on bringing the edges together. The wound was dressed with eucalyptic ointment.

25th.—Suffered no ill consequences from the wound in the throat, which is healing by first intention. There is still about an ounce of discharge from the chest. Melancholia still present.

April 2nd.—Wound in neck healed. Tube to be removed from chest in a few days. Patient up for the last few days; much stronger. Left the hospital this afternoon against advice, as he is still very weak.

On making inquiries as to the patient's present condition, it was ascertained that he had retrograded, and now resented any interference. His mental condition seemed to be much worse. In the words of the gentleman who saw him, "He seemed scarcely himself," and was the cause of much trouble and anxiety to those attending on him.

Remarks by Dr. SQUIRE.—It is now fortunately rare to see an empyema that has been allowed to burst through the chest wall. This burst at the point most commonly selected—namely, the fifth interspace anteriorly, between the serrations of the serratus magnus. The long continuance of the disease made permanent cure almost impossible; but free exit for the pus gave much relief, and the almost entire cessation of cough after the operation fully justified its performance. The weakness due to the long and wasting illness at last resulted in melancholia.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

A CASE OF INCISED AND PENETRATING WOUND OF ABDOMEN, WITH PARTIAL DIVISION OF SMALL INTESTINE; PUNCTURE OF SIGMOID FLEXURE IN ONE, AND OF MESENTERY IN FIVE, PLACES; COPIOUS HÆMORRHAGE; COLLAPSE; DEATH; NECROPSY; REMARKS.

(Under the care of F. H. WIGMORE.)

FOR the notes of this case we are indebted to Mr. R. Hamilton.

G. M——, a fine, healthy-looking man, aged twenty-nine, was admitted on July 23rd, with an incised and punctured wound of the abdomen, two inches and a half long, and running obliquely downwards in much the same situation as the incision which is usually adopted for ligature of the left common iliac artery. About six feet of the small intestine protruded through the wound, and lay upon the abdomen, while the mesentery, bleeding profusely, was tightly nipped in the incision, and thus prevented any backward flow of blood into the peritoneal cavity. The general condition of the patient was one of great pain, prostration, and collapse. No time was to be lost. It was necessary to control the hæmorrhage. The man was therefore placed at once upon the operating table and ether administered. The mesentery was punctured in five places—in one torn from the small intestine, which at that spot was bruised, though not lacerated to perforation,—and the hæmorrhage from these was prevented by the introduction of five ligatures through the substance of the mesentery, including in their tightened loops the bleeding vessels. The gut was then examined, and found to be cleanly divided through half its circumference. With a continuous suture of catgut the edges were brought into apposition. In two places the bowel was slightly bruised. The whole of the protruding gut and mesentery was carefully washed with a warm solution of perchloride of mercury (1 in 2000), and returned to the abdomen. There was no hæmorrhage, effusion, or fæcal extravasation into the peritoneal cavity, and the wound was closed in the usual manner with silver sutures. The spray was used throughout the operation, and a dressing of salicylic wool applied. At one stage of the proceedings the collapse was very extreme; the pulse failed, and the general aspect of the patient was that of impending death. A hypodermic injection of ether (fifteen minims), hot flannels, and an enema of two ounces of brandy to some extent rallied him, and he was put into a warm bed, with hot bottles. The temperature immediately after operation was 96°, pulse 160, and respiration 50.

As the collapse continued, two drachms of brandy were ordered to be given every quarter of an hour, with a hypodermic injection of ether alternating with them, and the continuous application of hot flannels. Any diminution in this stimulation caused an immediate failing of the pulse. After three hours and a half the general condition was to some extent improved. The bowels were moved twice during this period; the stools contained no blood. He passed his urine without instrumental interference. At 9 P.M. (five hours after the operation) he began to complain of nausea, and the stimulants were reduced and a grain of opium given. At 10 P.M. the temperature was 98°; pulse 120; respiration 47. At 10.30 A.M. he vomited, and this recurred eight times up to 1.55 A.M., when it ceased. Ice to suck, iced milk in very small quantities, and two drachms of brandy were given every hour. The pulse frequently failed, and this was met by hypodermic injections of ether. At 12.35 he complained of great abdominal pain, and an ice-bag was applied and continued until 4.25 A.M.; it gave him some relief. At 3.30 the temperature rose to 98·4°; pulse 150; respiration 27. At 7.30 A.M. the bowels were again moved. After this hiccough commenced; the temperature fell to 96·4°; pulse 84; respiration 46. At 9.50 A.M. he became quite collapsed and died, consciousness remaining with him to the last.

Necropsy by Mr. DIXON.—The abdomen was not distended, but retracted. The wound was healthy. The under surface of the great omentum was found slightly adherent to that part of the small intestine involved in the injury, and the coils here were themselves slightly matted together by threads of plastic lymph. There were no signs of repair in the wound of the gut. The bowel had sloughed in two places opposite points at which the mesentery had been tied to stop hæmorrhage, and corresponding with the bruises noted above. On lifting the intestine, fæces were extravasated through these perforations. No extravasation had occurred during life. Two small clots of blood were discovered adhering to the mesentery. A further examination disclosed a puncture of the sigmoid flexure close to the rectum. The perforation was just large enough to admit a probe of medium size, and was surrounded by a greenish slough, the outer margin of which passed into a congested zone, gradually shading off into the natural healthy colour of the contiguous gut. The other organs of the body were healthy.

Remarks.—This case illustrates very well the great and lasting collapse which immediately follows a serious injury to the abdomen and some one or other of the contained viscera, and the difficulty there is in rallying the patient from this condition of utter prostration. It might be interesting to note what part is played by mental emotion in the production and continuance of shock, and whether in such a state it is better to administer ether or chloroform when necessity requires an anæsthetic. When the patient's mind is quiet, large and grave operations may be performed without any of these serious and distressing symptoms presenting themselves. In this particular case the deceased was pursued some distance by a man who held a two-edged table knife, with which he intended to perpetrate the act he subsequently accomplished. The deceased is said to have turned round and met the knife in its descent, and then to have rushed about the street, crying out, and with his intestines protruding. Here, at any rate, mental emotion must have been considerable; and when his depositions were taken his pulse failed at the sight of the prisoner, and his already grave condition was aggravated. During the operation the pulse and general state became worse, and this notwithstanding the hæmorrhage had stopped and ether was administered. Under the careful use of chloroform in cases of this kind, a marked improvement has taken place. The exhibition of opium

Digitized by Google

or morphia in cases like this is a great part of the recognised treatment. The pain, vomiting, and the passage of three stools all pointed to an injurious activity of the gastro-intestinal tract; but after consultation it was agreed that the prostration contra-indicated its present use. The usual difficulty in the administration of stimulants arose here, as it does in cases of a like or diverse nature. The effect of the brandy upon the pulse was watched with extreme care. This case is one in which the use of stimulants was advantageous. Too often they are given in set doses, and not increased or diminished as the fluctuating circumstances demand. Thus the end of their beneficial tether is soon reached, and no further stimulation is possible. Besides, after a certain point is arrived at, which will vary with each individual, the stimulating effects of alcohol give place to symptoms closely approximating narcotism. The sloughing of the gut where bruised is of interest, for the bruising alone did not seem sufficient to account for the death of the part. It seems strange that, with so free an intercommunication between the vessels, the cutting off of the blood supply to so slight an extent should have operated adversely. Had the bruising not been present, the mere tying of the vessels would not, in all probability, have produced the results discovered at the necropsy. Had the bruising alone been present, it does not appear as an adequate cause of such an end. Again, would it have occurred if shock had not brought all vital processes to a minimum? This opens up that important question, still shrouded in so much, but lessening, obscurity, What part is played by nerve force in the development, production, healing, and nutrition of the human tissues?

Notices of Books.

The Commonhealth. A series of Essays on Health and Felicity for Every-day Readers. By BENJ. WARD RICHARDSON, M.D., F.R.S. London: Longmans, Green, and Co. 1887.—The great and general interest which attaches to all questions of sanitation is much enhanced when these are, as in the work before us, presented to the reader in a simple, free, and lucid style. The twelve lectures contained in this volume derive an additional charm from the fact that they are largely concerned with those aspects of hygiene which appear in the round of every-day life. They are not free from the pleasing mirage of poetic enthusiasm, the sometimes too fervent hope of fresh conceptions, but they also abound in tried wisdom and shrewd practical suggestion. The first, entitled "The Seed-time of Health," conveys some excellent advice respecting the management of children, that part of it which deals with the evils "inflicted" on the health of childhood being particularly noteworthy. In two following discourses recreation is made the subject of careful treatment. If at times the author seems to strain somewhat his argument against certain forms of exercise, as when he asserts that no positive good has accrued to the public health from the Volunteer movement, and condemns wholesale as dangerous rowing, football, and polo, there is much that we can cordially endorse in his downright reprobation of the feverish excitement, the overdone competition, and the practice of laying wagers, which accompany so many amusements and mar their good effect on mind and body. It must also be admitted that after all exceptions there remain many forms of healthful recreation which receive a word of warm approval. Physical exercises as a part of our national system of education are discussed with a due appreciation of their value. The chapters on school work, indeed, contains many other practically useful suggestions. "Cram" receives, as might be expected, unsparing condemnation; and there is wisdom in the remarks which inculcate on parents and teachers the duty of studying the constitutional types of children, in order that they may regulate their training accordingly. The subject of Dress is treated in some detail, with commendably free criticism of the existing code of fashion, but in a tone equally commendable for its moderation. There are chapters on the Diseases of Public Life; on Women as Sanitary Reformers—a useful treatise, requiring of women, perhaps, too deep an insight into physiology and hygiene for any but a leisured few to attain to or apply, though not more than is desirable; on the Poverty of Wealth, advocating neither poverty nor wealth but a happy mean, on Cycling as a Health Pursuit, and on Felicity as a Sanitary Research. We have not space at our disposal to discuss the merits of these various papers. Each of them is well worthy of perusal, and readers, if they find in them not a little debatable matter, will also find much that is instructive in itself and pleasing in its presentation.

The Laws relating to the Adulteration of Food and Drugs. By WILLIAM JAMES BELL, B.A., LL.M., Barrister-at-Law of the Inner Temple. Printed for private circulation by Walter Eyre, New-square, Lincoln's-inn. 1887.—It would have been better if Mr. Bell, to whom we already owe a useful treatise on the Sale of Food and Drugs Acts, 1875 and 1879, had published this thesis in the ordinary way; for it is calculated to be useful to all who are interested in the subject of adulteration. It may be divided into three parts—the first historical, the second descriptive, and the third critical and suggestive. The historical portion, though short, is exceedingly clear. Adulteration is spoken of by Pliny, and has in England been made the subject of many enactments; but no comprehensive law was passed until after public attention had been drawn to the matter by THE LANCET in the well-known reports of the Analytical Sanitary Commission, which commenced in 1850. The history of the present Acts follows, with a summary of their provisos and an excellent criticism on their shortcomings. As we have often pointed out, the gravest defects of the Acts are the want of fixed standards and the extreme irregularity of the machinery for enforcing analyses and securing due punishment for offences. Finally, we have a series of sensible suggestions for the amendment of the present law, and are glad to be able to agree with most if not all of them. We should indeed prefer, as Mr. Bell does, that a new Act be passed, and that it should be wide enough to cover all adulterations, including those of butter; but we do not deny the possibility of meeting some of the present difficulties by an Amendment Act, which should confer more stringent powers upon the Local Government Board, as well as upon local authorities. On one point we must dissent from Mr. Bell's opinion, for we cannot see how the public is to be protected against the sale of very inferior milk, unless some limit of strength is fixed by law. Of course the fixing of such a limit unfortunately implies permission to water or skim down to it, but that is freely practised at the present time, and cannot be stopped by inspection or analysis. We can only hope, in conclusion, that if Mr. Bell does not publish his thesis, he will at any rate include it in the next edition of his book.

The Asclepiad. No. 15. Vol. IV.—This number is appropriately devoted to the Jubilee purpose of showing the advancement of medicine under the auspicious reign of Queen Victoria, and it gives a good epitome of the great advancements made in practical medicine, preventive and curative, by—as Dr. Richardson neatly and with true Imperial purpose phrases it—the Victorian Faculty of Physic throughout the empire. From a humane point of view, doubtless, the author is right to give the first place to the advancement made in the treatment of the insane; we feel disposed to think, however, that what the author terms "the *second* great advancement of practical medicine" should have been assigned the first place, and chiefly on account of the utilitarian principle; for the proportion of actually insane people is fortunately small, whereas the benefits of preventive medicine are practically universal, and the application of results achieved in this sphere must

Digitized by Google

benefit the whole of civilised mankind. Even from a standpoint of nobleness of aim and splendour of achievement, preventive medicine should, we think, be assigned the first place. Indeed, it is clear that Dr. Richardson would not largely disagree with us on these points, for we find him writing: "Medicine, in her practical handiwork, never did anything more noble than when she put her hand to prevention." Attention is properly paid to the importance of the step which was taken in 1837, when on a sound basis a public and systematic registration of births and deaths was instituted, and when a weekly publication of mortality-returns and of the causes or diseases by which death was brought about was begun in good earnest. But with the advancements in preventive medicine it would be more fitting to deal in another place than in a notice of a quarterly journal. A high place in the record of advancement is necessarily assigned to anæsthesia, and with admirable fitness the biography of this number is concerned with one whose achievements were made in the several departments of advancement, and whose name will long live as a worthy type of the English scientific observer—Dr. John Snow.

Militärmedicin: kurze Darstellung des gesamten Militär-Sanitätswesen. Von Dr. H. FRÖLICH, K. Sächs Oberstabsarzt, 1 Cl. Braunschweig: Friedr. Wreden. 1887. (*Military Medicine: a short Exposition of Universal Military Matters.* By Dr. H. FRÖLICH, First Class Chief Staff Surgeon of the Saxon Army. Brunswick: F. Wreden. 1887.—As a handy book of reference, Dr. Frölich's work will be very useful to military surgeons of every country—at all events, to those of them who read German. After a short historical account of the literature of the subject, including references to Deuteronomy, Egyptian papyrus MSS., and Greek and Latin authors, a voluminous list of works published in various countries during the present century is given. The body of the volume consists of chapters on the *personnel* of the medical services of different armies, military medical education, recruiting, hygiene and diseases, and statistics of various kinds. Descriptions, with occasional illustrations, are given of various methods of transporting the wounded, and of arranging field hospitals and tents generally. The rations and clothing of the different armies are described, and a tolerably complete list of the more important works and papers on the different special subjects is appended to each chapter. The index would be more useful if it were more detailed. A good description is given of the arrangements at Netley, more space being allotted to this than to any continental military medical school.

An Address to Asylum Attendants "off Duty"—Invalided. By the Rev. HENRY HAWKINS, Chaplain of the Middlesex Asylum, Colney Hatch.—This little work supplies a want which must often have been felt by asylum chaplains and superintendents. It contains words of comfort for sick attendants, and advice to them during their illness to set their house in order and to sympathise with their fellow-sufferers. It should, we think, be distributed to the attendants in asylums, not only when they are ill, but when they are in good health; and if they take the kind words contained in it in a grateful spirit, it would doubtless have a practical effect upon their lives and actions. Attendants as a class are not only healthy in body, but also conscientious in the discharge of their duties. But there is no reason why we should not make attempts to improve them, as suggested in this pleasant little volume, which has been so carefully written for their benefit.

The Misuse of Marriage: A Voice. London: Remington and Co.—The aim of this little book is chiefly to denounce unequal marriages—namely, those between old men, who may have led immoral lives, and young girls. The author states that such marriages are reprehensible from every point of view, frequently entailing domestic scandals and divorce cases, and inflicting injury not only on the wives but on the children. He remarks, "When I see the legitimate requirements of a woman's nature trampled under foot by selfish and unprincipled men, it does not require any profound knowledge of physiology, psychology, or any other ology to say her offspring must suffer. I have heard over and over again from the mouths of the young that they cannot help this or that besetting sin or maniacal outbreak of passion, and it has caused me no wonder when I reflect how many children are infamously begotten, not only *in* sin, but *by* sin." He also states he has heard women remark that they do not mind what a man's previous life may have been if he remain true to them after marriage. To this he says: "To think that the past life of one half in making a whole does not affect the other half is one of those delusions which accompany vicious moral teaching. There are scientific reasons, I maintain, for what I advance in this paragraph. The impure life of one has often been the physical ruin of the other, and still more often the cause of the foulest moral pollution." On this point it is impossible to speak too strongly, and women would consult their own interests, that of their children, and the highest interests of society and morality, if they refused to marry or to give their daughters in marriage to men who are known to have led distinctly immoral lives.

La Chirurgia Renale (Renal Surgery). By Professor ANTONIO D'ANTONA. Rome: 1887.—The *brochure* before us is an address delivered before the Italian Surgical Society. Professor D'Antona briefly but fairly reviews the subject from the time of Simon's (of Heidelberg) first operation in 1871 to the present time; he then discusses the diagnosis, symptoms, indications, and contra-indications, and the methods of operating, founding his observations on his own personal experience of nine cases. These include one case of tubercular kidney and one of sarcoma, both successfully removed. The address is interesting as a record of practice, although it does not contain anything either very startling or very new.

The Ten Tribes. By ALDER SMITH, M.B., F.R.C.S. Robt. Banks and Son.—Dr. Alder Smith has published in pamphlet form a paper he recently read before the Prophecy Investigation Society upon the Ten Tribes, in which he supports the view that they are to be looked for amongst a number of apparently Gentile nations. There is no question of a physiological or medical nature touched upon, but the paper is worthy of perusal by all who take an interest in ethnological questions as connected with the historical and prophetical portions of Holy Writ.

Lewis's Pocket Case-book for Practitioners and Students. Designed by A. T. BRAND, M.D. London: H. K. Lewis.—This is a convenient pocket-book, with pages so mapped out as to give at a glance, under the heading of the different systems, the principal symptoms and facts of any case, with a page or two to spare for comments, therapeutical or otherwise. It is short and compact, and presupposes brevity and concentration in the practitioner; but it seems calculated to supply a want.

MADRAS MEDICAL COLLEGE. — The anniversary of this College was held in July last, Deputy Surgeon-General Roe being in the chair. The report of the 52nd academical year of the institution showed a steady maintenance of its prosperity. A remarkable feature in the returns of the examinations was the large percentage of failures in the Primary. Of 78 candidates who went up for the first L.M.S. only 18 passed, the weak point in most cases being Practical Anatomy. In the Preliminary Scientific, again, of 15 candidates only 4 passed. These large percentages of rejections indicate a state of things which seems to require earnest investigation. An address was given by Surgeon H. A. F. Nailer, one of the professors, and the meeting was brought to a close by some useful remarks by the chairman to the past and present students of the College.

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

(FROM OUR SPECIAL CORRESPONDENTS.)

Per Anglo-American Telegraph Company.

ON Wednesday, the 7th inst., at the meeting of the *Surgical* Section, an important discussion took place on Laparotomy, following various papers on this subject, on Gastrotomy, and Foreign Bodies in the Œsophagus. Amongst the speakers were Dr. Richardson (Harvard University), and Dr. Sayre (New York). The Treatment of Abscesses from Diseased Vertebræ formed a subject of debate by Mr. Edmund Owen (London), Dr. Sprengel (Dresden), Mr. Chavasse (Birmingham), Dr. Lange, and many others.

In the *Medical* Section, the Natural History of Disease was introduced by a paper by Dr. Ouchterlony (Louisville), and gave rise to an animated discussion, in which Drs. Arnold (president of the Section), Hemingway, Scott Bell, Pavy, and others joined. A paper by Dr. Cerothers (of Hartford, Conn.) on Diseases Induced by Inebriety gave a historical *résumé* of the subject. The author regarded inebriety as a central brain disease, and always associated with brain and body degeneration, largely inherited. The tendency to inebriety often followed, directly or indirectly, from disease or injury. The symptoms of direct physical causation were very common, but often masked. Treatment in hospitals he believed to be a necessity. Inebriety was a complex psychosis. It was increasing in the United States, and required very careful study and treatment. A good discussion followed the reading of the paper.

In the *Hygienic* Section, Dr. B. W. Richardson (London) read a valuable paper on the Growth of Preventive Medicine in Great Britain. Dr. Friere (Rio Janeiro) brought forward the subject of Vaccination in Yellow Fever, and exhibited specimens and preparations showing the microbe of the disease. He extolled vaccination as a prophylactic against yellow fever, and declared it to be safe and efficiently protective. At the conclusion of the discussion on this paper it was resolved: "This Section recommends co-operative investigations of results from inoculation as a protective, and that the Governments of various countries should assist in the work." Dr. Seaton (Chelsea, London) read a paper on Metropolitan Defences against Infectious Diseases by means of Hospitals, Ambulances, Ships, &c. The chief difficulty in London, he said, was the multiplicity of authorities. In the provinces it was much better.

In the *Obstetrical* Section, the discussion on the previous day's paper on Cæsarean Section was maintained by Professor Simpson (Edinburgh), Dr. Martin (Berlin), Dr. Headley (Melbourne, Australia), Dr. Doleris (Paris), and others. In the afternoon the subject of the Relation of the Atmosphere to Puerperal Fever was introduced by Dr. Kucher; that of Puerperal Septicæmia, by Dr. Madden (Dublin), in a paper read by Jaggard; and that of the Intra-uterine Douche and Curette in Puerperal Fever, by Professor Earle.

In the *Gynæcological* Section, the question of the treatment of Uterine Fibroids by Electricity was brought forward by Dr. Cutter, which gave rise to a lengthy discussion. Dr. Graily Hewitt then read a paper on the Relations of Changes in Tissues and Changes in the Shape of the Uterus. Gynæcologists, he said, were often reproached because displacements diagnosed during life were not disclosed at the necropsy. Chronic metritis covered a large number of conditions. A softened condition of the cervix uteri, due to loss of tone, was often associated with flexion, and arose from want of general nutrition. This softness, occurring at puberty, might disappear as health was regained or became permanent. Undue softness might lead to chronic metritris, but was not the disease itself. He quoted approvingly Dr. Mary Jacobi's study of endometritis, and thought the affection to be exceedingly rare. Dr. D. W. C. Wade, speaking on displacement of the uterus, put his remarks in the form of axioms, some thirty-nine in number, and dwelt upon the importance of such conditions, the necessity of examination, and the adoption of means for their relief. He made his own pessaries of copper wire covered with soft rubber. Results of Operation of Shortening Round Ligaments for Displacement of the Uterus, was the title of a paper read by Dr. W. L. Reed, of Liverpool. He had operated in thirteen cases. He quoted the opinions of a number of operators, the bulk of whom were adverse to the operation. When the perineum was destroyed, it might be advisable to perform this operation preparatory to other methods. Seven of his cases operated upon were successful. Dr. J. H. Kellogg made some observations on uterine displacement corrected by modifications of Alexander's operation. He had performed the operation twenty-two times, and believed it to be indicated in marked displacements of the uterus either backwards or forwards. The procedure might also be found beneficial in displacements of the ovaries, and might, he believed, frequently be substituted for extirpation of those organs.

The evening of Wednesday was devoted to social festivities. A garden party was given in the charming residence of ex-Commissioner Mr. Josiah Dent. The presentations were made by Dr. Ruth, of the United States Navy. The beautiful grounds were crowded with visitors. In the course of the evening receptions were held to foreign members by representative and Mrs. Glover; also at Mr. Thomas Wilson's. The elegant suppers were attended by streams of guests from 8 to 12 o'clock. The members of the Dental and Oral Section were entertained at dinner by Dr. Baxter, medical purveyor to the United States Army, and Dr. A. R. Robinson (New York) entertained the dermatologists at an elegant banquet.

On Thursday the fourth general meeting was held, at which Professor Unna of Berlin delivered his address on Dermatology. He spoke of the relation of dermatology to general medicine and of the interest the subject should have for the general practitioner, as skin diseases entered so largely into his work. Dermatology was a branch of pure science, but in that respect it was still young, and would require the conscientious labour of ardent competent observers before it could take the rank it merited. Serious difficulties had hindered a proper study of skin diseases, and had prevented many from devoting themselves to it. From time to time men of distinguished ability had taken the subject in hand and had given themselves up to it. Under their fostering care great progress had been accomplished. This department of medicine required special organisation for its study and treatment. It had a physiology and pathology of its own. What was wanted was a central organisation where the subject could be studied as a whole, where morbid symptoms, structural alterations, and the general course of disease might be watched. There were diseases due to external causes, constitutional condition, season, climate &c., in all countries, races, sex, and age. Among externa agencies, parasites occupied a most important place in nosology, probably because the effects were visible to the naked eye. The proper study of dermatology would do much to advance other branches of medicine, both surgical and medical, the position and relation between them being intermediate. The Professor recommended, instead of making experiments on animals for pathological and physiological purposes, that human skin should be used. He quoted numerous experiments made in this way tending to prove that this method had already led to the discovery of new facts. The founding of additional lectures and the establishment of private laboratories were required in order to carry out the proper investigation of the phenomena of skin disease. This branch would ultimately become one of the most important departments in the study and practice of medicine. He expressed a hope that the Government of the United States, with its accustomed liberality, would be the first to see the necessity for changes such as he had suggested, and put them into practice.

In the *Medical* Section the subject of Morphology of Rheumatic Blood was introduced in a paper by Dr. Cutler of New York. 1. The form of elements found in the blood of rheumatic patients he classified as follows: (*a*) Oxalate of lime; (*b*) cystinic; (*c*) phosphatic; and (*d*) uric acid. 2. The peculiarities of the red blood-corpuscles and serum, including thrombosis and embolism. 3. Lantern illustrations of the pathogenesis of albuminuria. Professor Semmola spoke on points of Treatment in Typhoid; Dr. Shingleton Smith on Diabetes; and Dr. Pavy, of London, to a very large audience, described the condition of the blood in the disease, the experimental induction of diabetes, the best modern test for the presence of sugar in the urine, the early diagnostic signs, and the best method of treatment. The diet should consist of meat, butter, cheese, and a little milk and almond

Digitized by Google

bread; whilst the medicinal agent to be employed was opium or codeine.

In the *Surgical* Section, the discussion on Dr. Richardson's paper on Gastrotomy was resumed. Dr. Assally of Bucharest extolled the merits of iodol in surgery. He said that, externally, iodol retards suppuration, deodorises and hastens healing; it was efficacious in chancres, and was superior to iodoform. There was no unpleasant odour, and it was not toxic in its effects. It was good internally in secondary syphilis, in paracentesis, and the early stages of hip-joint disease.

Mr. Edmund Owen (London) read a paper on Endocranial Surgery. Professor Durante of Rome read an interesting paper on Cholera Infantum. Dr. Maxwell of Florida showed that the usually assigned causes were not sufficient to account for it; they were only contributory, not proximate. The true cause was not yet known; it would probably be found to be a micro-organism. He advocated the use of steam as a disinfectant.

In the *Gynæological* Section Dr. Bell read a paper on Vaginal Extirpation of the Uterus for Carcinoma; Dr. Jackson one on the Modern Treatment of Uterine Cancer; and Dr. Treholme, one on Extirpation of the Uterus for Bleeding Myoma.

In the Section of *Obstetrics* a long and animated discussion was continued on Puerperal Septicæmia, in which Professor Simpson of Edinburgh, Dr. Graily Hewitt, Dr. Cameron of Montreal, and others shared.

In the Section of *Diseases of Children* an elaborate paper on Nutrition of Infants was contributed by Professor Leeds of New Jersey. The author divided his subject into (1) a brief statement of the present condition of our knowledge on this topic; (2) the presentation of results of original analyses of food in its natural state, and as artificially altered by simple treatment, or as compounded and manufactured articles; (3) composition of fluids, &c., used in nutrition, and as actually made ready for immediate use; (4) the alteration of foods by keeping, or by the action of therapeutic agents or preservatives; (5) comparison of results of analyses and experiments, with deductions therefrom; (6) conclusions and practical recommendations. Finally, Professor Leeds made references to the experiments on the digestive ferments carried out by Sir William Roberts.

In the evening there was a buffet banquet at Pension Hall, at which over 4000 persons were present. The magnificant interior was gaily decorated with flags and banners, the noble Corinthian columns being draped with American flags and those of other nations. The electric light fountain was also shown, whilst excellent music was furnished by the Marine band. The crush at the tables of refreshments was rather severe at times. Dr. Burnette entertained the foreign members in the Ophthalmic Section at a dinner; whilst the American members of the Nervous Diseases Section showed a similar hospitality to their foreign *confrères*.

On Friday, at the fifth general session, an address was delivered by Dr. F. Blandford of England on the Treatment of Insanity in Private Houses and in Asylums. The paper gave various typical cases of mania or dementia met with in practice, suggested modes of treatment, and described many cases of mania that could be treated successfully at home if the family were willing to defray the cost entailed. The author believed that nine cases out of ten should be removed to a more suitable place than an asylum. As regards treatment, to harness a patient to a bedstead by his wrists or ankles was not treatment at all. Unfortunately, even in this day, such practices were occasionally adopted. He spoke of the reluctance felt by relatives of persons needing treatment to sending them to an asylum. Non-asylum treatment of persons suffering from depression or melancholia had generally been tried before the services of a specialist had been called in. But asylum treatment was necessary in most cases of suicidal patients, though, as shown in the reports of the English commissioners, confinement in an asylum would not always prevent suicide. Melancholia was the most tedious of all curable forms of insanity. Weeks and months were often required to effect improvement in the condition of such unfortunates. Here the question of expense came in. In the case of poor patients, to properly care for them at home involved great expense to keep them free from old surroundings, which were likely to aggravate the malady. Exaggerated egoism was a noticeable feature in such cases. At home, where the patient was the centre of attention, this was encouraged. In an asylum, on the other hand, where the patient became one of many, where he sat at table with some twenty others, no one seemed to care whether he refused food or not. For many, therefore, asylum treatment was the best, as it involved what he would call judicious neglect. Speaking on the question as to how far it was possible to treat cases outside an asylum without recourse to lunacy laws, he thought physicians ought to have the opportunity of treating such cases outside an asylum until it was deemed by them necessary to seek asylum treatment, since recovery might take place in some cases without recourse to an asylum.

Many of the Sections were but thinly attended. In that of *Medicine*, a paper on Atypical Typhoid was read by Professor Dabney of Virginia. He divided his subject into the following sections:—(1) Typhoid fever is atypical in respect of temperature; (2) typhoid fever is atypical in respect of eruption; (3) typhoid fever is atypical in respect of intestinal symptoms; (4) the causes of atypical forms of typhoid fever, which were *(a)* climate, *(b)* season, *(c)* complications, *(d)* individual peculiarities, *(e)* prevalence of other diseases. He then described the morbid anatomy of the disease, and concluded with observations on the diagnosis, prognosis, and treatment in atypical forms of typhoid fever.

A paper, entitled Considerations on the Pathogenesis of Diseases in Women was read by Dr. William B. Neftel of Chicago, in which he gave a description of a series of experiments on animals, with the object of investigating the effects of pulmonary compression in favouring the development of tuberculosis. He found the morbid condition produced by experiments to consist in arterial anæmia and venous stasis. The same condition occurred in women from tight-lacing, causing a predisposition for settlement and proliferation of the bacillus tuberculosus. The author alluded to certain pathological considerations which support the hypothesis. The International Medical Congress was requested to appoint a committee to investigate the whole question of dress for women.

On the subject of Diphtheria in Canada, introduced by Sir James Grant, the speaker stated that diphtheria was prevalent after a mild winter with little snow.

An important report was made by the committee appointed to examine Koroski's paper referring to statistics published by Dr. Keller, physician to the Austrian railways, in which he attempted to prove that vaccinated persons die in greater proportion than unvaccinated. Koroski undertook the laborious task of examining and checking Keller's figures and their sources, and as a result the committee now reported that Keller's statistics were utterly false and untrustworthy.

In the *Military and Naval* Section many interesting and able papers were read on Thursday. The proceedings, moreover, were enlivened by a pleasing incident—namely, the presentation of an elegant vase of onyx, framed in gold, to Dr. H. Smith of Philadelphia, the president of the Section. Inspector-General Lloyd of London took the chair, and Deputy Surgeon-General Marston and others spoke in complimentary terms of the general hospitality shown by their American brethren, and by Dr. Smith in particular. Dr. Marston said, speaking for the foreign guests, they would be profoundly ungrateful if they did not highly value all that had been done for them in America. He could wish nothing better or more pleasurable than to introduce Dr. Smith to his friends and their families in England as a specimen of a true American gentleman. Dr. Smith in reply, said he must not forget to observe that the members of the Executive Committee were as worthy of praise as himself. If his efforts had not been so warmly seconded in London and on the Continent the success of the Congress would not have been so conspicuous. He warmly acknowledged the action taken by British physicians to neutralise malicious misrepresentations by those who were willing to cast discredit on his country and his profession in order to gratify personal pique. He could not better express his regret at their course, of which he spoke more in sorrow than in anger, than by applying to them the words of the Wizard of the North:—

> "Breathes there a man, with soul so dead,
> Who never to himself has said,
> This is my own, my native land,"

At the general sessions the Secretary-General of the Congress, Dr. Hamilton, reported that the Committee of Representatives of all the European nations present had unanimously selected Berlin as the place for next meeting, in 1890.

Digitized by Google

In the evening the foreign members and their ladies were entertained at a reception from 4 to 7 o'clock at Grasslands, the luxurious seat of Mr. Secretary Whitney.

On Saturday, the concluding day of the general session, votes of thanks were given to the President, General Secretary, &c., by representatives of the various European countries, who spoke in the highest terms of the manner in which they had been received. Dr. Graily Hewitt and Mr. Edmund Owen of London spoke for England. The meeting concluded with a farewell address from the President, who in a few eloquent and touching words remarked that, if alive, he would attend the Berlin Congress. In the morning the members went to Mount Vernon, Washington's burial-place, and nearly 400 left the same night for Niagara. The total number of members was 2760. A large photograph was taken of members in a group on the steps of the Treasury House. The meeting on the whole was successful, in spite of many eminent men holding aloof. The papers were numerous, but, with few exceptions, of not very striking merit. Hospitality was not quite so abundant and profuse as at London and Copenhagen, many wealthy citizens being away from Washington for the season. The officials, from the Secretary-General downwards, have done all in their power to make the Congress a success and to afford a hearty welcome to foreigners, but the working details of organisation would have borne improvement, very little pecuniary help having been given by the Government.

The ninth International Medical Congress has now dissolved, having met on Saturday morning simply to adjourn. The meeting was fixed half an hour earlier than usual, so that foreign members might catch the train to take them to Mount Vernon. Secretary-General Hamilton was busy at the table ten minutes before President Davis requested the attention of the meeting. The Secretary-General then presented the resolutions adopted by the Sections, which he said would be printed in the Transactions. Amongst these resolutions is one by the Section of Climatology proposing the establishment of national bureaus of vital statistics, one by the Section of Military Surgery relative to the prohibition of explosive projectiles in warfare, and one by the Section of Hygiene on teaching hygiene in public schools.

Dr. Graily Hewitt (London) said: "I come before you as one of the foreign members of Congress who have been requested to express in a few words the appreciation felt by the foreign members of Congress of the efforts made by the executive in furtherance of the objects of the meeting; we beg to convey our thanks for the attentions bestowed on us, and our appreciation of the success which has attended their efforts. I desire to express our sense of the hospitality, kindness, and attention, both public and private, received at this great meeting, attentions which will contribute to make our visit to Washington a source of congratulation and happy memory in the future. I beg to submit the following on the part of the foreign members of Congress:—'We desire to convey to the President of the United States our best thanks for his presence at the ceremony of the inauguration of this Congress, and we desire to express to the Executive Committee of the Congress, particularly to Dr. Henry H. Smith, Dr. John B. Hamilton, Dr. A. Y. P. Garnett, Dr. Tonen, and Dr. Arnold, our high appreciation of the efforts made for the efficient organisation, action, and working of the Congress, which have rendered it so great a success; and we convey our warmest thanks to the citizens of Washington for the kind hospitalities, public and private, we have received during our pleasant visit to this beautiful city.'"

Dr. Martin (Berlin) expressed in German his thanks for the kindness he and other members of Congress had received, and his gratification at the success of the Congress. He had come with some doubts, but these had all been removed, and the great success of the gathering would secure it a high rank among the medical Congresses which had been held. It was the custom to engrave the names of the victors at the Olympic games on plates of gold; they could not so record the names of their entertainers, they could only mark the expression of their sentiments by a vote of thanks.

Dr. Landolt (Paris), addressing the Congress in French, said: "I have been commissioned to express to the President of the United States our sentiments of profound gratitude; although unable to find words suitable to the occasion, I accepted the honour, and, since gratitude springs from the heart, there is no need of eloquence to make it understood. Mr. President and gentlemen, we have already assisted at a series of International Congresses, and have been well received everywhere. The countries of Europe have rivalled each other in zeal to make our stay with them in their beautiful cities pleasant, but not often has it been our lot to see the Chief of the State mingle in person among us, and take part in our labours. The President of this great Republic came among us to speak a welcome with sympathetic voice; he invited us to his own home, and gave each a hearty grasp of the hand, significant of the most cordial hospitality. The sanction given by President Cleveland to the Congress has imparted the greatest charm to our stay in this capital, and, returning to our hearths, we shall preserve the most grateful and respectful remembrance of the President of this great Republic, and say to the whole world that the United States, being so favoured, possesses, above everything, a chief who directs them surely on the way to progress and prosperity."

Mr. Edmund Owen (London), in a speech which was vociferously applauded, his references to Mrs. Cleveland especially meeting with hearty favour, said he desired to second Dr. Hewitt's resolution. In science there were no politics, and he was extremely happy to have visited the United States during the presidency of Mr. Cleveland. He asked an American friend, a very intelligent man, if he voted for Mr. Cleveland. His friend said "No." He asked him if he was satisfied now, and received the laconic answer, "Guess I am." If that question were put to this meeting—Are we satisfied? I say, "I guess we are." A man like the President might have found something else to occupy his attention—say, in the White Mountains—this time of year; he might have been driven away by the doctors, but instead he remained to welcome them. "When the history of this grand country comes to be written, we trust President Cleveland will have a niche in the temple of fame side by side with those great men, Lincoln and Garfield. When you are in our country, we love to hear you say, 'We admire your Queen.' We say in all truth, we admire, we love your Queen of beauty and grace. In seconding this vote of thanks, I simply express the prayer that Mr. President Cleveland and Mrs. Cleveland may long continue in strength and health to preside over a happy, prosperous, and united country." Dr. Hamilton, Secretary-General, then presented Dr. Hunt of this city, on behalf of the Section of Oral and Dental Surgery, with a handsome gold-headed cane, as an expression of appreciation of his courtesy.

Dr. Hamilton replied to the speeches of the foreign delegates, and said: "Mr. President, I could not fail to be deeply sensible of the great kindness bestowed upon me, and the many words of encouragement received during the present meeting and the past six months. I am profoundly grateful for the expressions now placed upon record; but, sir, the success of the Congress is due to no one man; all on this side worked with the spirit and enthusiasm of Americans, whose hearts were in their work; but all efforts would have been in vain, and the strongest would have failed, had it not been for the noble army of scientific men abroad who, deaf to all misrepresentations of disappointed factionists, came from the universities of old England, the vine-clad hills of France, the seats of learning of Germany, the cities of the Alps, from sunny Italy, the lowlands of Holland, the fastnesses of the Danube, from far-off but ever-near Russia, from the golden shores of China, from Japan, Cairo, and the sands of Egypt, and the everlasting hills of Palestine. I say to these representatives here assembled that to them we owe a debt of gratitude which time cannot efface; as these, our dear colleagues, braved the dangers of the deep, and sustained in some cases the shock of calumny in order to be with us, so let us here say that when again we meet at Berlin in 1890 let it be to renew friendships formed here, and once more grasp the hands of those who have been true to us now."

Dr. Davis (President) after referring to his professional life of more than half a century, said one of the objects of his life had been to promote harmony among all branches of medicine; to-day the happiest feeling of his life was that he could now stand here in the capital of the United States, and not only see the profession he loved united and working harmoniously, but stand among representatives of almost every country of the globe. He thanked those who had come across the water to attend the Congress, not only in his own name, but in the name of the profession of America, in whose name the Congress had been invited to sit here. There were members of the profession from every State in this great union assembled to greet the foreign members, of whom there was a larger gathering

Digitized by Google

in this Congress than in any one preceding. He thanked the members of Congress for the courtesy shown in sustaining him in the discharge of his duties. "Life with me," he said, "will not be long, but if it is spared with sufficient health I shall feel great satisfaction in meeting my friend Dr. Martin and all his comrades in Berlin in 1890."

The Niagara excursion proved an unqualified success. Two special trains, with sleeping cars, left Washington on Saturday evening. They stopped *en route* at Watkins' Glen, a wild, rocky mountain gorge, which was rendered additionally interesting by numerous torrents and cascades. The scene altogether was weird and beautiful in the extreme. Niagara was reached on Sunday night. The visit to the rapids was made on Monday, when all the several spots from which a view of the falls from both sides could be obtained were visited. To the foreign members hotel expenses, railway fares, drives, and everything were free. An impromptu meeting was got up at Niagara, Dr. Pavy in the chair. A resolution was proposed by Dr. Coghill (Ventnor), seconded by Surgeon-General Rayer (Russia), and supported by Surgeon Langridge and others, acknowledging the magnificient hospitality shown to the foreign visitors by their American entertainers. A vote of thanks was also passed to the organising committee with much applause.

It is understood that the next Congress, to be held at Berlin in 1890, will be presided over by Professor Virchow.

ERRATUM.—In our last issue, page 540, first column, the name of the author of the paper on Sunstroke was wrongly printed "Langridge," instead of Anderson.

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

ON January 1st, 1887, there was a total of 822,215 paupers in England and Wales, and, compared with the corresponding date in the previous year, this exhibited an increase of 2116 in-door and 7144 out-door paupers. The increase ranged from 3·8 per cent. in the north midland division to 0·6 in the south midland division, the largest numerical increase being that of 3575 in the metropolis. In referring to the causes of this increase, it is stated that it has to some extent been brought about by the increased number of sick in the Poor-law infirmaries, where improved treatment and care has led to an undoubted lengthening in the lives of the sick, and into which the poor, who have a great reluctance to the workhouse as such, have no objection to enter. As regards the expenditure on poor relief, it appears that in the last financial year there was, as compared with the previous one, an increase in 13 unions, amounting in all to £36,520, the largest being an increase of 6·9 per cent. in the York union; and a decrease in 31 unions, amounting in all to £231,890, the largest decrease being one of 6·6 per cent. in the metropolis. The cost per head on the mean number of paupers of all classes was £10 12*s.* 6½*d.* for England and Wales and £22 5*s.* 2½*d.* for the metropolis.

In the Local Government and Public Health Department of the Board returns have been issued showing that since the constitution of the Board in 1871 sanction has been given to the borrowing of £36,722,067, and this mainly for sanitary improvements. Of this sum, £31,249,949 has gone to urban districts, and £2,378,331 to rural districts. During the same period power has been given by means of local Acts for raising £43,759,711. The principle of repayment of a moiety of salaries for medical officers of health and inspectors of nuisances seems to be increasing, and at present such repayment is made as regards 1163 of the former and 1067 of the latter officers. In certain instances this repayment is withdrawn, and such was the case in a certain number of instances in which the Board refused to sanction proposed reductions in salaries; indeed, the report before us makes special reference to the inadequacy of the salaries frequently proposed by sanitary authorities, and it is pointed out that one of the objects of the grant is to secure the appointment of efficient officers, and the proper discharge of their duties. Such repayment is now also extended to increases of salaries granted to medical officers of health and inspectors of nuisances to whom duties under the Dairies, Cowsheds, and Milkshops Order, 1885, are delegated.

With reference to defaulting authorities, the case of Cheshunt is of somewhat long standing, and at present the issue of the mandamus which was obtained against that Board is still deferred, because the authority have acquired a loan of £15,000 for the compulsory purchase of land for their sewerage works. The other cases mainly bid fair to come to a satisfactory solution, although in some instances difficulties have to be contended with. Near Canterbury the city wells are apparently open to pollution by reason of certain cesspools just outside the city boundary. The rural sanitary authority appeared ready to remedy the mischief by draining into the city sewers, but the Town Council have refused the necessary permission. In the meantime, such risk as exists must remain.

A large number of port sanitary authorities which heretofore were only appointed temporarily have now been placed on a permanent footing, an arrangement which must necessarily promote our organisation for the improvement of the sanitary state of vessels and crews, and for preventing the importation of disease from abroad. This work of permanent port constitution is still in progress, and expenditure is going on around our coasts as to port officers, hospitals, &c.

Under the Sale of Food and Drugs Act, 1875, we find that during the past year one sample was analysed for every 1181 persons, and that, in London, St. Mary (Newington) stands alone in sending in an absolutely *nil* return. This local inaction has been marked ever since the commencement of the Acts, and a dairyman in the adjoining parish, and who was fined, somewhat naturally complained that he only watered his milk to the same extent as a neighbour and rival, who was allowed to adopt this form of competition because he happened to live on the other side of the way. There were also three counties and sixty-six boroughs in which no single sample was submitted for analysis during the year. Of samples analysed, the highest percentages of adulterations were — spirits 17·8, butter 17·3, coffee 15·1, pepper and milk each 13·0, mustard 12·7, and drugs 10·8; the total proportion of adulterations being 11·9 per cent. of articles analysed, as opposed to 13·2 last year—indeed, it is the smallest proportion as yet reached. As regards milk, the report expresses a fear that some of the apparent gain is attributable to the lowering of the analyst's standard, and not to an improvement in the milk; and it refers to the difficulty of deciding between a milk that has been fraudulently watered and a genuine sample from a badly fed cow; indeed, it is well known that many dairymen adopt the practice of watering rich milk down to a limit which will pass the test. The analyst for the city of London points to a real difficulty when he states that public analysts have come to the conclusion that as yet "none of the processes of analysis in general use ensure uniformity of results." With respect to butter, there is evidently a steady increase in the sale of so-called butterine, mostly manufactured in Holland. The worst feature of this sale is that the butterine is bought by butter manufacturers and mixed with butter, to the sole advantage of those guilty of the fraud. Butterine, or rather, to give it the legal name, "margarine," itself is usually a wholesome article of diet.

The vaccination returns show clearly where failure to comply with the law in this respect mainly lies. In the provinces a somewhat steady increase in default is going on, the births not finally accounted for in this respect being 5·3 per cent. in 1884; but the evil is principally located in the following unions, where the percentages are excessive: Keighley, 71·7 per cent.; Leicester, 47·9; Dewsbury, 37·6; Derby, 29·4; Henley, 19·2; Oldham, 17·2; Barrow-on-Soar, 15·2; and Eastbourne, 15·2. It will need a "day of reckoning" to convince these people that their children have a right to the possession of the same protection against small-pox as they themselves have. The calf-lymph station may fairly be regarded as meeting the case of such objectors as can assign a reasonable ground of objection; and we are glad to learn that during the year 5329 persons resorted to it. A large amount of animal lymph was also distributed from it. Reference is made in the report to a number of other subjects. These include a summary of the medical work, but as to this a separate report is annually issued by the medical officer to the Board.

THE Chelsea Board of Guardians, on the recommendation of a committee appointed to examine into the condition of the post-mortem room of the parish, have decided to pull down the present structure and erect a new one.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 17, 1887.

THE history of the London scarlet fever epidemic has entered on a new phase since the extraordinary meeting of the managers of the Metropolitan Asylums Board on Saturday last. Scarlet fever is steadily increasing, and, so far as can be judged from former experience, both the extent of the epidemic and the mortality are likely to become aggravated during the next two months. London is, however, provided with a body having special powers, organisation, and resources for dealing with infectious diseases in such a way as to minimise their danger to the community, and yet at a critical moment in the course of an epidemic they meet, they talk over the prospects before London, and end by passing a resolution which, in so far as it is not altogether meaningless, is directly hurtful to the interests of the inhabitants of the metropolis. In five weeks the admissions from scarlet fever into the Asylums Board hospitals had increased from 91 to 195. The Asylums Board had available for that disease 1282 beds; 1045 of those beds were occupied early this week, and the fresh admissions are daily on the increase. Fortunately, there is a large new hospital at Winchmore-hill, which, if utilised pavilion by pavilion as the need arises, could be properly fitted for the sick in about a fortnight, by which date the 200 beds still available elsewhere may be expected to be occupied. In the face of this emergency, the managers, having first decided by a vote of hands to defer all consideration of the subject for the very period of a fortnight which gave them their only chance of doing their duty, ended by a formal vote of "the next business"; and then they wended their ways homeward, leaving London and scarlet fever prospects to take care of themselves.

We are quite prepared to admit that there are many matters which call for modification as regards the duties and responsibilities of the managers of the Metropolitan Asylums Board Hospitals, but to avail themselves of such an opportunity as the present one to discuss these subjects indicates, to say the least, a defective sense of public duty. One manager wants to limit the length of the period of detention in hospital, so as to return the patients back to the public precisely in the stage in which every tyro knows them to be obviously infectious and dangerous. Another utilises a scarlet-fever emergency to raise questions as to the reception of non-paupers, and as to the need for recovering expenses from those who can afford to pay. A third would diminish the amount of floor space per patient, and this, too, at the moment when it is proposed to take the convalescents away, and so to aggregate together, with diminished air space, those who, above all others, need ample breathing room. Such are the matters that came under discussion at Saturday's meeting, and they will not fail to have convinced the London public that, after all, there must be something radically wrong in the constitution of the Metropolitan Asylums Board itself.

We would for the moment limit ourselves to two points in which it is evident that the constitution of that body needs amending. In the first place, it is essentially a Poor-law body, and as such it is unfitted to deal with the important sanitary considerations which are referred to it. The Poor-law element is always raising its head at meetings where matters affecting the health of the metropolis are under discussion, and at which representatives of the sanitary authorities are markedly absent. This point was especially alluded to in the Report of the Royal Commission on Small-pox and Fever Hospitals, and a reorganisation of the Board was declared to be necessary. But year after year passes, and nothing is done to remedy the anomaly. In the second place, the Board have no medical adviser. Had the matters dealt with at last Saturday's meeting come before the town council or local board of any ordinary English town, the recognised adviser in matters affecting the health of the town would have been present; he would distinctly have informed his authority of the extent of the danger and of the measures necessary in order to meet it; and in the face of his skilled advice it would hardly have been possible for the most retrograde body to have dealt, as the managers of the Metropolitan Asylums Board were compelled by a majority of their number to deal, with an emergency such as London now has to meet, and this unaided by the very body whose duty it is to cope with the difficulty.

Possibly the minority found themselves hampered because a number of their colleagues who are not tied by Poor-law notions happen to be away from the metropolis at this time of the year; but it is to be hoped that an effort will be made to call back such members as can be trusted to place the welfare of the metropolis before all other minor considerations, and that a second meeting will be summoned. In the meantime, we can only hope that the increased readiness on the part of the population to resort to hospitals tends to give to the rapid increase in the number of admissions a more serious meaning than the actual circumstances would otherwise justify.

As the area of knowledge extends and its depth increases, facts, as we know them, wear different aspects and things seem to change; and as the transformation proceeds the old names and formulæ become obsolete or acquire new significances. Practically to-day systems and schools, so called, of medicine have died out, and all that relates to the method or principle of the art of healing may be grouped under two heads—namely, Rational Medicine and Empiricism. It is not worth while to recall the historic or traditional meaning of these terms. The sense in which we employ them is the common as distinguished from the technical or scholastic. By rational medicine we mean that which consists in the reasonable and purposive use of agents to do certain specific work which is upon ascertained grounds held to be necessary or conducive to the remedy of disease and the recovery of health. There is no mystery in this method, nor does it include or imply any purpose or procedure which is not in accordance with the laws and processes common to all science and art. The medical scientist does not deal in any special art or mystery. He proceeds on common-sense principles, and by logical methods of inference lays down his plans

Digitized by Google

and carries them out by plain and obvious means and agencies. He is a scientist of the same school and type as other scientists, and he works in medicine precisely as they work in other departments—for example, geology, zoology, or physics. In proportion as he is a sound practitioner of medicine is he a rational scientist; and, as a matter of fact, if a scientist from any other department engaged in the specialty of medicine he would need only to deal with the new sets of facts in the old methods. This is the test of all true science in art, that the method of work is the same, however widely the province of labour may differ; and it follows that the labourers in the divers fields can understand each other, help one another, and mutually criticise and correct each other's endeavours. Rational medicine is sound in proportion as it is *orthodox* not in the sense of being conformable to any special canon of truth, but in accord with the universal principles of science. The attempt to set up any special hypothesis or to lay down any particular law is in itself an act of revolt against science, and stands self-condemned as irrational. Thus if *similia similibus curantur* were not a fallacy, it would hold good throughout the whole domain of science—not in medicine only, but in every department. Its character as a proposition in which an essential part of the theorem is suppressed is a self-evident proof of its heterodoxy. No one ever alleged that the similarity of the *similia* extended to their quantitative as well as to their qualitative properties; and as the formula did not express this limitation, it omitted to state an essential part of the truth, and so became a false statement of the worst possible kind—in short, a fallacy; the truth suppressed being that all agents act differently in different magnitudes or doses, and that therefore *similia* in one dose must be dissimilar in other doses, and the doses in which they were or were alleged to be, administered were not the doses in which they were similars. This, apart from all the superadded fallacies of infinitesimalism and the like, which have emphasised the grotesque absurdity of "Homœopathy," would alone place that so-called *system* of therapy outside the pale of rational medicine, and the like is true of all other systems. Whatever and wherever a claim is set up for any method or scheme of principles as peculiar to the art of healing, the fundamental law of rational medicine, as a branch of science, is violated, and either the pretence is idle, or the theory on which it is based is unsound.

The fact that rational medicine is an integral part of science as a whole, and conformable to its universal laws and principles, formulates many minor facts interesting alike to the profession, the practitioner, the student, and the public. For example, it follows that all the old exclusiveness is at an end, and that as the knowledge of nature becomes more widespread among the people, the profession must needs stand on a simple footing of specialty in science—that is, greater acquaintance, and consequent expertness, in dealing with a particular class of facts, and nothing more. As we said just now, the medical scientist differs only from the scientist in geology in that he has made the facts grouped for convenience under the heading "Medicine" the subject of his special study as a scientist, instead of directing his attention to the group of facts designated "Geology." He is neither more nor less a scientist than his compeer in other departments. It follows, again, that the practitioner of medicine must practise in conformity with methods and upon principles common to all practitioners in the several branches of science; and therefore his work must be easily understood by them and amenable to the scrutiny of competent critics in general science, if only they will take the trouble to make themselves acquainted with the special facts of medicine. Again, the student must needs be grounded in the principles of general science and acquainted with its methods before he takes up the specialty of medicine. There can be no such thing as an exclusively medical education; and while the student of medicine must be first a student of science, no student of science can find the door of medicine barred against him, or find that the key of knowledge does not open this department as easily as any other. Further—and this may, in some senses, seem to be the most pregnant of the consequences dependent from the fact that rational medicine is an integral part of science—the confidence of the public in the profession and its practitioners is likely to be ultimately measured by the status in science which they attain, rather than by the successes they achieve in the struggle against disease. It will before long come to be perceived, and even now it is beginning to be seen, that the prestige of the profession as a whole and the reputation of its members do not so much rest on what they do as upon what they *are*. The System and the Charlatan may catalogue their successes and parade them as the grounds of a claim to public respect and confidence, but as medicine assumes its true place as a branch of science and its practitioners are regarded as men of science, this appeal must not only appear incongruous, but by the force of circumstances prove to be no longer of any avail. This is the hope we have of the regenerating power of truth. As science sways in medicine, it will become less and less a craft, and at length develop into a purely scientific art, stripped of all unworthy disguises and simply rational. We see the same change coming over all branches of applied knowledge; and true progress must sooner or later—the sooner the better for ourselves and the community at large—bring rational medicine into the closest and simplest relation with other branches of science until knowledge becomes one.

Empiricism is the antagonism of all this. In its modern sense, at least, the term empiricism may be taken to mean wilfulness, in ignorance or defiance of law. The essence of empiricism is an assumption of exclusive skill in the individual. It is not even the idea of exclusiveness in knowledge of the sort which may for a time exist, when, of several competing practitioners in any art, one may attain to a deeper insight of principles, around which he casts a mystery. The empiricist in medicine affirms his power and right to employ remedies discovered by some genius of his own. He does not hold himself bound to account for their modes of action even to himself, still less to others. It is enough for him that they serve his purpose, or that he thinks they will do so. He tries experiments, and if they succeed he repeats them without any feeling of responsibility to determine by what law his procedure is governed. He is of the same mind as the counsel who cares nothing for the soundness of his legal argument if only he can win his client's suit. It is as though

the mariner should care nothing for astronomy, or magnetism, or the laws of winds, and currents, and storms, if only he reach safely the port for which he is steering. Of course there is no science in the method of the practitioner of this class, and, except in so far as he is blindly using the brains of better men, there is nothing of science in the system on which he works. Probably all empiricism is really at bottom a fraud, and those who pretend to exercise it are, knowingly or unconsciously it may be, acting upon suggestions emanating from authorities who are not acknowledged. In any case, as a method or system, empiricism, as we see it around us to-day, is one of the most contemptible and mischievous of the uses to which men—sane and honest men—can put the faculties of will and sense. To do an act without knowing or caring why it is done, except that a certain result will probably be attained, is to fall back on that elementary process of reasoning by which the lower animals arrive at the conclusion that they must eat to live, or seek cover for shelter in a storm. *Experientia docet* is a maxim at the very initial point of mind-work. The outcome of such work can at best be only the heaping together of facts in confusion. Science is in no way advanced by such labour, though it may chance that the accumulated results of experience will sometimes supply the scientist with materials he would otherwise need to go further afield to obtain. Even if it be granted that the empiricist does now and then seem to strike a lode of valuable ore, as by a divining rod, the fact that his success is not achieved by the working out of any *rational* process of applying knowledge not only deprives him of all claim to the character of a scientist, but obviously affords no ground of expectation that he will be able to repeat his enterprise. The empiricist is isolated. He has nothing whereby he can link himself with others. He does not himself know how or why he is successful, and his success affords no ground of confidence. On the basis of empiricism nothing can be built. The sum of knowledge is not increased by it, and the pursuit of science is rather retarded than advanced, for men are led to trust to chance for the gifts of genius, instead of setting honestly and intelligently to work to win the knowledge of facts according to natural laws.

It is of the highest moment that those who are commencing the study of medicine should recognise the fact that only rational medicine is a branch of science; and it would be well if those who practise medicine could be induced to make this fact a cardinal point of their philosophy, with all the intellectual, actual, and ethical considerations and consequences it implies.

WE published last week a communication from a correspondent on the subject of the medicine stamp tax, from which it appears that the Revenue authorities have recently been applying the Act under which it is levied with peculiar stringency, in all probability urged by the old patent medicine proprietors. The time is therefore opportune for a renewal of the protest which we have often before made against this antiquated, unjust, and even pernicious form of taxation.

There would be ample ground for invoking legislative interference if only to readjust this tax on the ground of its unequal incidence. For the upshot of various statutes and their judicial interpretation has been to reduce the law at the present time to a state of utter confusion. The original Act of GEORGE III., by which medicines were rendered liable to duty, was couched in the most comprehensive terms. These were made subject to various exceptions by subsequent Acts of Parliament, with the object and general effect of excluding from the category confectionery and beverages. One of the repealing Acts, however, was so worded that when it came to be construed by the Court of Appeal in the well-known case of the ATTORNEY-GENERAL *v.* LAMPLOUGH, it was held that the administration of a medicine through the medium of artificial mineral water entitled it to exemption from the duty. The Revenue Commissioners, again, have adopted of their own motion the view that preparations which are administered by burning and inhalation of the fumes are not to be regarded as "used or applied externally or internally." Such preparations are accordingly treated to exemption also, and in the result it is matter of the merest chance whether a particular medicament will be held to be liable to duty or not. We quote from our last week's correspondent (p. 545):—

"Chemists are prosecuted for selling simple pharmaceutical medicines which have not the slightest resemblance to patent medicines—e.g.: simple quinine, made up into pills by means of sugar, gum arabic, glycerine, or other excipient; quinine pure and simple, enclosed in a capsule of gelatine or covered with sugar; rhubarb, made into a fluid extract or tincture by extracting its properties with alcohols; menthol, dissolved in spirit to form a solution; powdered rhubarb and soda triturated together are under certain conditions held liable. The Board of Inland Revenue rule that each of the before-mentioned, or the mixture or combination of any two or more drugs, or the addition to a drug of any other substance (although it be but a vehicle or adjuvant), are thereby removed from the category of 'medicinal drugs—entire' (or crude drugs), and become nostrums, liable to the stamp tax, in each and every case where the medical properties are stated upon the label, or set forth in advertisements to the medical profession and chemists in medical and pharmaceutical journals. All compounds and mixtures of the Pharmacopœia come under this ban according to this arbitrary ruling, and the chemist vending is liable to a heavy fine if he states the medical properties upon the label, or in any advertisements to the medical profession or trade."

In the LAMPLOUGH case two courts gave judgment for the Crown, and only after a most elaborate legal argument did the Court of Appeal pronounce in favour of the defendant. That the tax collector should be turned loose upon the public with a weapon like this in his hands is not only a grievance crying loudly for redress; it is a disgrace to the statesmanship of our Legislature, and one which, without distinction of party, it concerns all politicians who lay any claim to enlightenment promptly to remove.

But this is the least of all the objections to this impost. On fiscal grounds it is difficult to conceive of any objection to any tax which cannot be urged against this one. Should taxes be apportioned to the means of the taxpayer? The bulk of this tax is collected from the poor. Should the payment of a tax be arranged with a view to the convenience of the taxpayer? This one is levied in times of sickness chiefly. It is collected, therefore, at a time when the payment of anything in the nature of a tax constitutes a peculiar hardship, when the ordinary expenses are increased by the demands made upon a poor man's purse for special food and the like, and when perhaps the ordinary income is

Digitized by Google

reduced or even suspended altogether in consequence of the patient's incapacity for work. Thus in the time and circumstances of his greatest need this additional burden is cast upon him, and his convenience is studied only for the purpose of its being outraged. And, finally, should the collection of a tax be economically done so that as little as possible may be taken from the pockets of the community beyond what goes into the exchequer? This is collected in the costliest way imaginable. The manufacturer or importer advances it in the first instance, and treats the money so laid out as part of his capital expenditure, on which he will, of course, expect to obtain his ordinary trade profit. This he secures by charging the wholesale dealer with the duty *plus* his ordinary profit, in addition to the cost-of-production price. Of course, the wholesale dealer recovers his outlay in a similar manner, and with a corresponding further addition for trade profit, from the retailer, and the retailer in his turn reimburses himself at the expense of the consumer. The exchequer receives only the amount originally paid by the manufacturer *less* the ordinary expenses of collection; the taxpayer is mulcted in the whole accumulated profits of the various traders through whose hands his medicine has passed, in addition to this ordinary charge. Some years ago we showed by an analysis of figures that in this way a *sixpenny stamp* involves, in a very ordinary case, an addition of about *two shillings* to the retail price,[1] so that for the privilege of contributing something less than sixpence to the national exchequer the unfortunate taxpayer has to pay eighteenpence to the financiers whom the Government scheme interposes between himself and Somerset House. Surely there never was a tax more radically or incorrigibly bad. If any considerable proportion of our Imperial revenue had to be levied on such a method as this, the QUEEN'S Government could not be carried on for a single week. The only explanation that can be offered of the survival to our own times of an impost so oppressive, so unremunerative, and so unjust is that politicians have consented to regard it as a matter insignificantly small and to treat it with contempt. Small it may be from the point of view of the Chancellor of the Exchequer, for of the ninety and odd millions which he annually demands, it yields him very much less than one five-hundreth part. But from the payer's point of view it is anything but insignificant; for him it lays wait until his "rainy day" comes round, and falls with its tripled or quadrupled weight precisely at that time when the smallest addition to his outgoings is felt to be a serious burden.

But the worst feature of this tax has yet to be mentioned. Its uncertainty, its oppressiveness, its wastefulness, are much; and they are inseparable faults. But if it were desired to add to all these one crowning mischief, no better—i.e., no more mischievous—plan could have been devised than that of collecting the duty by means of a stamp. The stamp is nothing but an official receipt for duty paid; But again and again has it been represented by unscrupulous vendors as being some sort of Government voucher of the excellence of the nostrum with which it is sold. Mistakes of this sort are constantly being made by uneducated people. Within the present session there have been brought to the notice of the Government in the House of Commons repeated instances of the same kind of thing in the most diverse fields. And on all these occasions the mouthpiece of the Government has expressed a fitting sense of the duty which lay upon the representatives of the Crown to disavow these mischievous fictions, and take steps so far as possible to remove the appearance of official authority in their support. But never has the prestige of Government been more impudently or more profitably claimed than by some vendors of "patent" medicines that might be named. The class of remedies somewhat inaccurately termed in common parlance "patent" comprises, without a doubt, some of undeniable excellence; but it contains also many that are fraudulent and some that are deleterious. But for each and all of these an unscrupulous vendor may claim what virtues he pleases, and cite in proof of his claim the authentic Government stamp. True, his argument does not prove his conclusion, but it convinces a certain number of possible customers, and that is the material point in his view. That also is, we admit, *the* material point in our view. It is startling, it is scandalous, that the Government stands by, and for a paltry bribe of £150,000 a year becomes a party—a conniving party—to such wholesale and shameless fraud. If on fiscal grounds we urge the repeal of this obnoxious tax, on moral grounds we demand it. The present session is now over, but we shall make it our business to renew the agitation from time to time until the good cause prevails.

[1] See THE LANCET of July 5th, 1884, p. 22.

THE questions with which we propose to deal in discussing some points in connexion with hysteria have to do with that class of phenomena which some sceptical minds, especially in England, are apt to reject from careful consideration, or, if they accord any consideration to them, adopt a different explanation from that which is current amongst the French. We are tempted to recur to the subject because of the recent appearance of several new publications dealing with the subject matter, and especially we may mention the book of M. PAUL BERBEZ[1] and a paper by M. RENDU in the *Archives de Neurologie* (No. 41, vol. xiv.). In order to obtain a clear notion of the views which are pretty generally entertained on this subject in France, and which, we may add, are not without adherents in England, America, and Germany, it may be well to state a theoretical explanation of the alleged phenomena.

Of all the parts of the nervous system none is more impressionable than the cerebral cortex to changes of various kinds happening at the peripheral apparatus of afferent nerves, whether these be the special organs of sense or other less definite terminal organs. We do not wish to deny that this statement has not something of the nature of an assumption, but it is, we think, one which will bear inspection by the light of ascertained facts. Hysteria, if it has any special place and habitation, is most likely a derangement of certain areas of the cerebral cortex, but this is perhaps an even bolder assumption than the preceding. A further step towards understanding the present position of the subject may be taken by simply stating what are believed to be the ascertained facts of hystero-

[1] Paris: A. Delahaye et Lecrosnier, Rue des Carmes.

traumatism—the term traumatism being employed in the widest sense to signify any shock, wound, or concussion.

Certain predisposed organisms or individuals do suffer, or aver that they suffer, after the receipt of some traumatism from rather characteristic phenomena, which may take the shape of an unpleasant idea, a disagreeable sensation, or an emotion of the gay or sad kind, and not necessarily of the intense sort. Some of these impressionable individuals experience a fixed pain in one joint, or acquire a rigidity of a limb, or even a limp form of paralysis. Since such affections sometimes disappear entirely, even after having lasted for many years, we cannot reasonably regard their causes as of an organic nature; and furthermore it is highly improbable, considering the slight variations exhibited in the morbid phenomena, that a contracted or a dilated state of the bloodvessels of the faulty nerve centres can be the essential cause of the derangement. The belief that the genuine nervous matter has undergone some slight but effective change seems to us to be far more in accordance with the facts of nervous physiology, and we can think of no better analogy than the one which Dr. RUSSELL REYNOLDS employed long ago, and which conceives that nervous matter may be "magnetised and demagnetised," in the same way as iron may be, without altering in any considerable degree its essential constitution. The real cause, then, of hysterical paralyses, pains, and the like is the special state of the brain; and the occasional cause—i.e., the traumatism—can have but a slight action. We assume, therefore, that some individuals are morbidly mobile in the nerve centres—or, to keep up our analogy, we may say more easily "demagnetised" in certain parts of their cerebral centres.

It has been thought by some observers that the change in the cerebral centres is really and chiefly the outcome of the traumatism, which they conceive brings about a definite organic change of slight intensity—as, for example, the least possible ecchymosis. In cases of nervous disease ensuing on severe traumatism, as happens in railway accidents, such a hypothesis offers a perfectly possible solution of the symptoms; but at the same time, in addition to mere physical shock, hæmorrhages, and inflammations, there almost always exists a certain degree of psychical or hysterical disturbance, which intensifies and adds to the symptoms chiefly induced by the actual lesions, and this psychical element must vary with the individual, being of greater force in those who belong, or come nearest, to the group of hysterical, not to say neurotic, people.

For practical purposes the symptomatology and the diagnosis of these affections are by far the most important considerations. The symptoms are as varied in seat as they are in character, and the combination of them is also remarkable for its variability. The paralyses may be of the so-called *limp* kind (*les paralysies flasques*), or some stiffness may attend the paralysis (*les paralysies avec contracture*). The paralysis may be limited to one limb, or even to parts of a limb, or it may take the form of a hemiplegia or paraplegia. The diagnosis may be rendered more difficult by the absence of any history of nervous attacks or hysterical phenomena, and there may be even no affection of the special senses. Of this combination M. RENDU gives an interesting illustration in the case of a girl aged seventeen, who had an incomplete paralysis of the right hand associated with preservation of the electric contractility, but with loss of the muscular sense: "the absolute anæsthesia involved every form of articular sensation."

Perhaps the least well recognised forms of hystero-traumatism are those cases in which monoplegiæ constitute the principal nervous element. The following is an outline of such a case from E[illegible]REBEZ's book: A cavalier, aged twenty-four, without any family history of nervous disease or any personal history of nervous affections, sustained a fall from his horse on May 8th, 1884, and broke the radius of his right forearm. The splint was removed at the end of fifty days, when there was found to be, not unnaturally, some difficulty in moving the limb; this paralysis, instead of mending, increased to absolute loss of power of the whole of the right upper limb, which underwent no improvement for the better during the next four months. After this period a careful examination demonstrated the complete paralysis of motion and of sensation to pain, touch, and temperature, which anæsthesia extended to the deep parts of the limb, so that violent torsion of the limb was actually painless, and electrical currents of great intensity were borne without apprehension and without pain. The muscular sense was completely lost, but the muscular contractility was normal in the paralysed limb. The anæsthesia extended as far as the shoulder, and was bounded by a zone of diminished sensibility, so that the line of demarcation was difficult to establish. There was some contraction of the visual field of the right eye and abolition of the pharyngeal reflexes (anæsthesia), with preservation of the knee jerks and cremasteric reflexes.

THIS is the season *par excellence* of continental travel. A large number of our countrymen, including a good contingent of the members of the medical profession, are now engaged in clambering among Alpine snowfields and glaciers, or floating upon the fair lakes of Switzerland and Italy, or inspecting the art treasures of Munich, Florence, and Venice. The practice is one to be on the whole commended, although a word of passing regret may be expressed that so many go far afield for their pleasure and leave unexplored the scenes of great beauty and high historic interest in which our own country so remarkably abounds. But while continental travel, duly regulated and pursued with intelligent interest and with the pre-existing educational fitness necessary for its appreciation, may be in a high degree pleasurable and instructive, we are strongly of opinion that the average tour is often an unmixed failure, whether regarded from the point of view of health or intellectual profit. To many it is a time of worry and weariness, and to some a source of really grave impairment of physical strength. We propose to glance for a moment at some of its special dangers, which a little wisdom and experience should enable the traveller to guard against.

There is, first, the danger which so few escape, of over-excitement and undue physical effort. We attempt too much in our tours, and forget that the brain-worker, whether lawyer, physician, or merchant, is commonly out of condition and unfit to encounter severe fatigue. The man, who, after twelve months of continuous mental labour and little muscular exercise, posts from London to Chamouni or

Digitized by Google

Zermatt, and incontinently essays the ascent of Mont Blanc or the Matterhorn, is really guilty of an unpardonable forgetfulness of the conditions and limitations of healthful recreation. If he escape with mere fatigue and the sense of having misused his holiday, he will have reason to rejoice that he has not also overstrained his heart and done irreparable mischief. We have taken an extreme case, but in minor degrees this error is in daily and hourly practice during the holiday season. Mountain-climbing, while perhaps the most delightful and exhilarating of pastimes, has of course other and more special dangers. The unlooked-for fog or snow-storm, the treacherous path through the moraine, the sudden rush of the avalanche, have cut short many a happy and useful life. The list of fatal Alpine accidents has been this year unusually heavy, and their plain and pregnant lesson is the utter folly of even hardy climbers venturing unknown ascents without the assistance of trained guides. Mountain-climbing is, in fact, almost as much a special *métier* as the management of a ship; and practical training can be as little dispensed with in the one case as in the other. With proper help, this amusement seems to be as safe as any other form of vigorous out-door sport, in all kinds of which more or less risk is necessarily present.

Pedestrianism, whether mountain-climbing, or the less fatiguing walks among the valleys or in the open country, requires due regulation if mischief is not to result. The pedestrian should be lightly clad with some woollen material next his skin. He should not burden himself with much luggage, and he should pay special heed to his foot-gear. If a long journey be contemplated, an early start should be made, and ample time allowed *en route* for rest and refreshment. Snow-water, honey, and the fruit so freely offered by itinerant vendors are best avoided by the pedestrian in Switzerland, and universal experience proves that alcohol in any form is injurious during active effort. Coffee or tea may be drunk with advantage, and solid chocolate is one of the best sustainers, if regular food be not obtainable.

In whatever manner the traveller elects to spend the time of his tour, whether in mountaineering, or the more sedate pleasures preferred by the majority of tourists, the due regulation of food must occupy a considerable share of his attention. As a rule, the food of the continental *déjeûner* and *table d'hôte* is perfectly wholesome, but ordinary prudence would suggest the avoidance of the raw ham and sausage often offered in Germany, the use of which is unquestionably fraught with serious danger of *trichinosis*. The cold veal and salad, so popular on the Continent, are apt to be trying to feeble digestions, and although *vin ordinaire* is a very harmless beverage, it should not be consumed in large quantity by those unaccustomed to the use of acid wines. The drinking water at many continental resorts is undoubtedly open to grave suspicion, and the use of some standard and not too mineralised table water is to be commended. It is well for the traveller to remember that the ordinary *carafe frappée* and *siphon d'eau de seltz* are really made with ordinary town water, and that their use is therefore open to all the usual risks.

In former days a large proportion of the continental hotels were notoriously deficient in sanitation, but this is now rather the exception than the rule. The credit of this reform undoubtedly belongs largely to our own nation, which has always been impatient of sanitary defects, and has gradually succeeded in impressing its views upon other nations. Nevertheless, if the traveller stray far beyond the accustomed haunts, and especially if he penetrate where the English tourist is unknown, he should still be upon his guard.

An occasional source of danger, especially in Italy, is the unguarded passing from the blazing street into some chilly cathedral or picture gallery. The tourist should remember in such cases that any sensation of "chill" indicates danger, and should act accordingly.

With regard to railway travel on the Continent, the regulations are such as often to compel the use of the first-class carriages, and the traveller pays exorbitantly for such special comforts as the *coupé-salon* or *coupé-lit*. It is well for the tourist to recollect that in most cases he will be compelled to leave the train on crossing the Customs frontier, and care should obviously be exercised if this be at night. It is a common error to make the return journey home at express speed, and the more delicate class of travellers may in this way lose much of the benefit previously accruing from their tour.

Annotations.

"Ne quid nimis."

LONDON MORTALITY FROM SCARLET FEVER.

THE evidence afforded by the returns issued by the Metropolitan Asylums Board of a recent marked increase in the weekly number of London cases of scarlet fever admitted to those hospitals, renders it desirable to ascertain whether the returns of the Registrar-General show anything like a corresponding increase in the registered deaths from this disease. In the three decennia 1841-50, 1851-60, and 1861-70, the annual death-rate from scarlet fever in London was successively 0·86, 1·02, and 1·13 per 1000; the annual rates in those thirty years ranged from 0·35 and 0·41 in 1841 and 1846, to 2·12 in 1848, 1·84 in 1869, and 1·87 in 1870. During the more recent decennium 1871-80, the mean annual rate declined to 0·60, the lowest rate being 0·19 in 1873, and the highest 1·06 in 1875. During the forty-three years 1838-80 the death-rate from this disease fluctuated widely from year to year, showing epidemic fatality at four or five year intervals. Since 1880, however, when the rate in London was 0·82, it has steadily declined year by year to 0·18 in 1885 and 0·17 in 1886, these being lower rates than have been recorded in any previous year since the commencement of civil registration in 1837. In the first two quarters of this year this comparative immunity from scarlet fever in London continued, and the annual rate did not exceed 0·16 and 0·18 respectively. Moreover, notwithstanding the evidence of increased prevalence afforded by the Metropolitan Asylum Board returns, no definite increase in the deaths from this disease occurred until after the middle of August. During the first seven weeks of the current quarter ending 20th August, 159 deaths from scarlet fever were registered in London, while the corrected average number in the corresponding period of the ten years 1877-86 is 294. In the three succeeding weeks the registered deaths from this disease were 36, 39, and 53, the last two numbers being respectively 3 and 18 in excess of the corrected average. The annual death-rate from scarlet fever in London in the ten weeks ending Saturday, 10th inst., was 0·35 per 1000, corresponding with the mean rate from the same disease in the same period in

Digitized by Google

the twenty-seven provincial towns. It may be noted, too, that in the week ending the 10th, when the scarlet fever rate in London had advanced to 0·35, it was exceeded in Sheffield, Manchester, Birkenhead, Oldham, and Bristol. As might naturally be expected, the scarlet fever mortality varies greatly in intensity in different parts of the metropolis. The annual rate in the last ten weeks, which was 0·35 in the whole of the metropolis, ranged in the five groups of registration districts from 0·18 in the north, to 0·26 in the west, 0·34 in the east, 0·38 in the central, and 0·52 in the south. Not only the highest death-rate, but the largest increase upon the low rates in 1886, occurred in the south group of registration districts. If we further differentiate this mortality in South London, we find that the rate exceeded 1 per 1000 in the two registration districts of St. Saviour and St. Olave, Southwark, and further that still higher rates prevailed in the sanitary districts of St. George, Southwark, Newington, Bermondsey and Rotherhithe. From the above-mentioned facts it may confidently be assumed that up to the present time the increase of deaths from scarlet fever has been in no way proportionate to the increase of isolated cases.

INOCULATED TUBERCLE.

DR. LESER of Halle records (*Fortschritte der Medicin*, No. 16) an interesting case of tubercular infection of a wound. He says that the older writers were more persuaded of the possibility of such inoculation than present-day pathologists are. Thus Valsalva and Morgagni were particular to warn against the dangers of such inoculation in the necropsy of phthisical subjects. He reminds us also that the death of Laennec from consumption was attributed by his contemporaries to a wound on the finger received some years previously at a post-mortem on a tubercular case. The revival of such doctrines of late years has doubtless been greatly stimulated by the discovery of the tubercle bacillus; and accordingly we again meet with records of cases, of which the most curious, perhaps, are those respecting the transmission of tuberculosis in the rite of circumcision. (Lindeman, Lehman, and Elsenberg.) Leser's case is briefly as follows: A female, aged fifty-four, came under treatment for a large swelling in the right pectoral region. It appears that, born of a healthy family, with no trace of tubercular taint in its members, she had three years previously received a cut on the ungual phalanx of the right thumb, which she had simply bound up and not treated further. The wound did not heal, and after a time suppurated and became very painful. The skin ulcerated, and at the end of a year a similar ulcer appeared on the contiguous forefinger. Some time afterwards a swelling appeared in the region of the right breast, and attained a large size before the patient sought advice. This swelling extended from the clavicle to the nipple, and proved to be a large subpectoral cold abscess, which Leser evacuated and drained. The pus had a "tubercular character," and the walls of the abscess were lined by tubercular granulations. The lining was scraped out, and a portion of the third rib, which was bare, was excised. The condition of the thumb and forefinger now attracted attention; the ungual phalanx of each was greatly swollen, the skin undermined and in places ulcerated, but the bone not involved. The diseased parts were treated by scraping and excision, and in a few weeks the parts had nearly healed. Microscopical examination revealed typical tubercles and bacilli in the granulation tissue, whilst further examination showed the presence of an enlarged gland on the inner side of the arm, also tubercular; it was also learned that a small abscess had previously formed in this situation. The case thus appeared to be one of tubercular inoculation of a wound of the thumb; secondary infection of the forefinger; then dissemination by the lymphatics, terminating in the formation of a large subpectoral abscess. Dr. Leser says that cases of similar tubercular infection are nearly always to be found in wounds which have been neglected or in chronic ulcers, as if it required that the tissues should be lowered in vitality in order to render them susceptible of infection. He concludes his paper by refuting arguments against the tubercular nature of lupus, and cites a case in which he considers the dependence of lupus upon tubercular infection to be undoubted.

THE TRADES UNION CONGRESS.

THE Trades Union delegates, who met for their twentieth annual Congress last week at Swansea, did not fail to touch on several questions relating to public health. Some of the delegates complained of the bad ventilation of factories, especially where a certain amount of dampness had to be maintained to prevent brittleness in the threads used for weaving or spinning. Others insisted that the number of inspectors was altogether insufficient, and related how, in their own experience, Factory Acts and Sanitary Acts were alike disregarded. A plumber proposed a resolution to the effect that persons appointed to the post of sanitary or nuisance inspector should have some practical experience and knowledge, whereas, in a particular locality one sanitary inspector was a grocer and the other a publican. From a sanitary point of view, the most important discussion was that which related to underground bakehouses. Mr. Jenkin, of Manchester, said that, though he had made bread for thirty-five years, he had seen an inspector only five times. Nearly all the work was done at night, and then the inspectors did not visit the bakehouses. Mr. Parnell, of London, pointed out that the old Act was preferable, for then the inspectors were under Government; while at present, being appointed by the local authority, they were not so free from unfair pressure. The condition of some bakeries, both in London and Manchester, were stated to be such that if publicly described people would be afraid to buy bread. A resolution was unanimously carried calling on the Government to prohibit the building of underground bakeries, and to obtain the registration, as to proper sanitary conditions, of all existing bakehouses. Further, the Government is called upon to appoint as inspectors men who are well versed in the tricks of trade, and who, when small boys are hid in flour vats, will not conclude that there is no juvenile labour employed. Indeed, at the Trades Union Congress, as in so many other directions, we find the same complaint as to the supineness of local authorities. It is not so much that law is wanting, as that its application is always too leniently enforced. The workmen, who are the principal persons to suffer, have done well to call public attention to these questions.

MODEL DWELLINGS.

AN interesting account has been written by Mr. H. E. Armstrong, medical officer of health of Newcastle-on-Tyne, of a model dwelling which has been erected in the Royal Jubilee Exhibition of that town. The dwelling, which is detached, is built with materials and appliances which have been presented by different exhibitors, and everything is evidently of a very complete and perfect character. The house has been planned by Mr. R. J. Leeson, and consists of four rooms on each floor, which with the offices are well arranged. We understand that the building will remain permanently after the Exhibition is over, and will serve as a type of all that is good in house architecture. There is no doubt that it will be found of considerable use to the corporation, who, it may be hoped, will be able to exhibit it for the purpose of stimulating the erection of better houses than at present exist. It would be well if every town had the same opportunity of educating its inhabitants.

WOOLWICH AND SANDHURST.

THE Board of Visitors of the Royal Military Academy at Woolwich and the Royal Military College at Sandhurst appear determined to carry out, to the fullest extent the policy of suppressing all information respecting the health of the cadets in these two national institutions. In 1885 the reports of the medical officers, with returns—very meagre it is true—of the amount and nature of the sickness during the year, which had hitherto been published in the reports of the Board of Visitors, were omitted. In those for the past year no reference whatever is made to the subject as regards Sandhurst, and as to Woolwich there is only a recommendation respecting the provision of proper hospital accommodation in cases of infectious disease, and an observation on the absence of any suitable means of obtaining warm baths. There is no information whatever given as to the extent of sickness among the cadets or the diseases by which they have been affected. It is, no doubt, unpleasant to have public attention called to the evidence afforded by medical returns of the want of due care and regard to sanitary requirements in these important educational establishments, but the suppression of the returns removes a valuable check upon the remissness of those who are responsible for their efficient condition. The comments of the medical press upon the unsatisfactory state of health of the cadets, based upon the results shown in the medical returns, may be very disagreeable and displeasing to the military authorities and the Board of Visitors, but they have been made entirely in the interest of the cadets and their families. If there be nothing to conceal, no neglect to be overlooked, no petty false economy practised at the expense of the cadets' health, the Visitors will do well to restore to their reports, and even in a more complete form, the information which was formerly given. We would call the attention of the medical members of the House of Commons to this subject, in the hope that by a little judicious pressure in the next session the Secretary of State for War may be induced to direct that the requisite information be in future included in the reports.

THE GLANDERS BACILLUS.

DR. KRANZFELD gives (*Centralblatt f. Bacteriologie*, Bd. ii., No. 10) the results of his recent investigations upon glanders at the Odessa Bacteriological Institute. He first availed himself of material afforded by nodules removed ten hours after death from a case of acute human glanders. Cover-glass preparations of these nodules contained a large number of bacilli. Small portions from the centre of the nodule were introduced into the peritoneal cavity of two guinea-pigs. One of these animals presented marked infiltration at the seat of inoculation on the fourth day, and swelling of the left testis on the seventh day; it died on the fourteenth. A greyish ulcer with infiltrated margins occupied the seat of inoculation; the left testis was replaced by a caseous abscess, and the spleen contained numerous yellowish-grey nodules. The pus from these parts and the nodules of the spleen contained numerous bacilli, the ulcer yielding also various micrococci. Cultures on serum, agar-agar peptone, potato, and agar-agar peptone with glycerine were made. The growth of the bacilli on blood-serum and potatoes corresponded to the description given by Löffler. The glycerine agar-agar cultures were the best, whitish streaks appearing at the point of inoculation on the second day, reaching seven or eight millimetres in width by the sixth to the eighth day. The bacilli had the characteristic shape, with rounded ends, as described by Löffler. In the older cultures, some thicker, less regular rods, which stained badly, were thought to be involution forms of the bacilli. No spores were found, thus confirming Löffler's surmise that the bodies described by Weichselbaum as spores are due to the death of the bacillus. In a series of inoculations in guinea-pigs, carried through several generations, the characteristic disease of the testis, nodules in the spleen, and in some cases disease of the nose, were present. No other internal organ besides the spleen was found to be affected. A case is given where a diagnosis of glanders was made by bacteriology. Some nasal secretion from a horse thought to have glanders, but with no clinical facts in support, was sent to the Institute for examination. Guinea-pigs were inoculated with the material, and died in due course with the above lesions. Examination of the pus and of the splenic nodules showed the characteristic bacilli, which were also obtained by cultures. A post-mortem examination on the horse confirmed the diagnosis thus arrived at; it proved to be a well-marked case of pulmonary and nasal glanders.

CANNED SALMON.

A CORRESPONDENT draws our attention to the process of canning salmon for the British market as performed on the American Pacific Coast, which certainly appears to involve some risks against which the consumers of salmon are entitled to be warned. The operations are described in an article on the subject by our Transatlantic contemporary, the *American Grocer*, as follows:—

"The process of canning is very interesting and more intricate than one would suppose, beginning with the manufacture of the cans and ending with the packing in cases. The tops and bottoms are cut with great rapidity by dies, and the sides by a knife cutter. The sides are then rolled, six at a time, on a machine somewhat resembling a clothes wringer. They are then taken to the men who solder the seams, and from them to others who put on the bottoms with great dexterity and rapidity. A little piece of solder called a "float" is dropped into the can, and the hot iron is run inside, melting it and fastening on the bottom. There is also in use a soldering furnace and rimmer for fastening bottoms, similar to the one used for covers described later. The cans are now ready for use, after being carefully examined to see that they are perfect. We now go to where the canning begins..... The chunks [of salmon] are then taken to a number of choppers, who slice them lengthwise into a number of small pieces, when they are carried on trays to the fillers. These press the pieces into cans, filling them as compactly as possible. A Chinaman will fill 1000 cans in a day. The filled cans are then taken to the washing machines.....They then pass through the hands of boys, who set the tops on, and are taken to the crimper and soldering furnace. In this machine the edge of the cover is crimped, and the cans then roll across a brick furnace, the ends passing through a trough of melted solder, and continue down a wire tramway to the hands of the testers. The capacity of this machine is from 20,000 to 22,000 per day. The cans are then tested for imperfection by examination and immersion in hot water, and all not air-tight are taken to the solderers."

From this description of the cans it would seem that the bottom is attached to the side by an *internal* seam of solder. This would be unobjectionable if, after being manufactured, they were effectively cleansed before use. Indeed, it would in that case have its advantages. For the solder would protect from contact with the fluid contents the cut iron edge of tinned plate, which is, of course, apt to become oxidised and thus soluble to a greater or less extent. But it does not seem that this necessary cleansing is done, and it follows that some of the flux employed in soldering—presumably chloride of zinc—will be left to mix with the contents of the can. The same difficulty appears to arise in connexion with the operation of closing. For better expedition this is done by rolling the edge of the can through a bath of molten solder. The heating of the contents, which is inseparable

Digitized by Google

from such a method, must, of course, give rise to an outflowing current of the contained air, accompanied probably by more or less steam, from the half-dried fish. It is not surprising, then, that a staff of testers is kept at work to examine as to the soundness of the joint, or that a large proportion of the cans—it is said 25 per cent.—fail to pass the test. Our difficulty rather is to understand how any can is effectively sealed in this way. But "practice makes perfect," and no doubt the exposure of the tin to the solder bath is for a very brief time only. The 25 per cent. of faulty cans are despatched to solderers, who will of course drench them with chloride of zinc again, some drops of which are sure in these circumstances to find their way into the interior; the more so because it must often happen that the can when it comes into the solderers' hands is cooling down, and that consequently a minute indraught of air will take place through the chinks left in the seams, tending thus to carry in any liquid that may be cast upon them. Upon the whole, then, it is easy to explain both the bad condition in which much of this preserved fish arrives upon our market, and the deleterious effects that are too often traceable to its consumption. The American methods appear, from all accounts, to be admirably expeditious; but, for our part, we should be better pleased with the result, though obtained at a somewhat greater cost in time, if its preparation were marked by more scrupulous attention to details and the use of more scientific processes.

CONTAMINATION OF AIR BY MANUFACTORIES.

IN an age when the size and population of our towns are increasing with great rapidity under the stimulus of commercial and manufacturing enterprise, whatever tends to promote the wholesomeness of those great hives of industry becomes a matter not merely of comfort, but of vital concern, to those who dwell in them. Great towns are, indeed, full of customs and pursuits which are avoidable causes of injury to the public health. If we examine the present conduct of trade with a candid mind, however sanguine, we cannot but find in the general conditions fostered by feverish competition, in the too common mismanagement of mealtimes, food, recreation, rest, and atmosphere, proof enough to fortify abundantly the serious indictment we have made. It needs, indeed, no protest, no proof even, from us to bring home the practical force of that remonstrance against the wholesale neglect of sanitary rule which is marked in the pale face of many town-bred workers. The anæmic stamp of countenance is due to a variety of unhealthy conditions. Not least important among these is a scarcity of oxygen in the surrounding air, and the presence of impurities due to respiration in confined spaces, to coal-burning on a large scale, to sewer gas, and to the volatile or suspended products of manufactures. This too-prevalent anæmia is the mark of lowered vitality, and the very frequent forerunner of more decided illness. If, therefore, its causes can by any means be counteracted, the use of these is clearly advisable. Not a little has been done already by means of household ventilation and systematic house drainage to purify the air we breathe. In another direction very little indeed has been accomplished, though measures of reform are not only most desirable, but are likely in many cases to become, if carried out, an actual source of income. We refer to the refuse produce emitted by manufactories and work-fields. Notwithstanding the circulation of fresh air which is constantly flowing over town and country, it must be allowed that there is in many places an excess of noxious matter in the atmosphere above what is compatible with healthy life. Coal dust, iron filings, clay from potteries, carbonic gases from brickfields, sulphurous gases, and hydrochloric acid from metal and chemical works, besides ammoniacal vapours, nitrous and nitric acids, arsenious and other metallic fumes, organic gaseous products of decay, are still freely cast forth into the surrounding air. Their influence in the atmosphere is often plainly perceptible by the senses, and, if not as plainly poisonous, has, without doubt, its share in that subtle impairment of vitality to which we have referred. The question relating to atmospheric contamination from this source and its treatment is a large one, and deserving of consideration alike by economists, sanitarians, and the general public. In certain cases it may even, as Professor Foerster of Berlin maintains, come within the province of the Legislature. We are sure, however, that it could, at all events partially, be settled without such interference if employers of labour were more alive than they are to the loss they incur under the present wasteful and injurious system.

CHOLERA INTELLIGENCE.

WE regret to find that cholera in Southern Italy has exhibited a further substantial increase in severity. In Sicily 36 deaths took place in the province of Palermo in the week ending the 12th inst.; in the province of Catania there were 121 cases and 66 deaths, 74 and 31 respectively taking place in the town of Troina; and in Messina 173 cases and 64 deaths took place in the three days Sept. 10th to the 12th. On the mainland 40 attacks are reported from Naples, 17 deaths having taken place in the three days ending the 11th inst.; 9 cases and 7 deaths are also reported from Aversa and Fatamaggiore in the province of Naples. Fresh attacks are further stated to have occurred at Frosinone, Caserta, Teano, and Capua, in connexion with the movements of troops from an infected locality; Berletta and also Reggio, in Calabria, are still infected, and it is stated that attacks have occurred at Cagliari. From Malta the returns, although incomplete, are more reassuring. In the five out of seven days, when details were received, there were 43 attacks and and 29 deaths up to the 12th; but the disease exhibits no fresh tendency to spread. The British garrison remains unaffected, and it is stated that in many cases the disease is of a mild type. If this latter statement be correct, it must mainly relate to cases not included in the official returns, for the rate of death to attack shown in those returns indicates considerable severity of attack.

THE ALCOHOL CONGRESS AT ZURICH.

THIS has been a highly successful gathering, the attendance of physicians and statesmen being exceptionally numerous, while the general public took a warm interest in the proceedings. The official report, when published, will be found to contain valuable discussions on "Alcohol as Food," a subject on which the Congress came to a unanimous conclusion, denying absolutely its claims to alimentary value. On "alcohol" as medicine very diverse opinions were announced, and the question was left open. Dr. Dock (a Swiss physician) gave interesting details on vegetarianism, which, he contended, supplied all legitimate requirements of the human subject; and Dr. Fovel, of Zürich, whose specialty is medico-psychology, enlarged on the connexion between alcohol and mental derangement, in the treatment of which he insisted on total abstinence as a primary condition of success. Valuable statistics were adduced by Dr. Lammers of Bremen, and Dr. Rochat of Geneva, on the good work achieved by Temperance Societies and by the Blue-Ribbon movement; while Pastor Krapp, in the absence of his friend M. Miquel, gave a most instructive history of the "Twelve Years' War" waged in Germany against alcoholism. The Temperance Society, headed by Dr. Lammers, numbered 10,000 members, and the pressure such unions could bring to bear on Governments in raising the tax on spirituous beverages and thus restricting their sale

Digitized by Google

must, he anticipated, prove ere long effective. Meanwhile, the labouring poor were being more and more largely provided with people's halls and coffee-rooms, where intellectual and profitable recreation could be enjoyed without the temptation to indulge in the poisonous drinks so universally obtruded on them hitherto. Dr. Rindfleisch furnished gratifying proof of the efficacy of the Evangelical Total Abstinence Society, and showed that every creed had borne a hand in the work—not least the Jesuits, since the first establishment of their order.

THE ILFRACOMBE DISASTER.

IT is satisfactory to find that the inquiry by the coroner has been supplemented by one held at the instigation of the Board of Trade, which brings out in explanation of this shocking catastrophe some practical points, the observance of which may tend to prevent similar accidents. The report of the finding of the Court on which we write is probably not fully accurate, and is somewhat contradictory. But there are two or three important points on which it seems explicit. There was no reason why the vessel should have had so large a well in her centre. Life-buoys should be carried in some convenient form. It is suggested that the cushions of the seats might be made available as buoys. Thirdly, the Court found that the casualty was due to the main-sheet having been made fast, instead of being held in the captain's hand. We devoutly echo the hope of the Court that proper regulations may be made by some responsible authority for securing the observance of all the precautions recommended by the Court. Otherwise we shall only too surely hear of similar distressing accidents.

PREVALENCE OF SCARLET FEVER IN LONDON.

THE rapid increase in the number of scarlet fever cases under treatment in the Metropolitan Asylum Board hospitals has very reasonably attracted much public attention. The number of these cases, which had fallen in the middle of April to 368, slowly increased to 476 at the end of June, and has rapidly increased since that date to 1153 on Tuesday last, the 13th inst. It is evident that the value of these figures, even as an indication of the prevalence of this disease in London, depends in great measure upon the proportion which the cases treated in hospital bear to the total cases, and that they afford no indication of the mortality from the disease, which can alone be ascertained from the Registrar-General's returns. As regards the proportion of scarlet fever cases in London treated in hospital, it was pointed out in the Registrar-General's last Annual Summary that in 1878 only 7 per cent. of the deaths from scarlet fever were recorded in the Metropolitan Asylums Board and London Fever hospitals, while the percentage rose to 13·2 in 1883, 17·6 in 1884, 20·2 in 1885, and 22·7 in 1886. This steady increase in the proportion of London scarlet-fever cases treated in hospital has been regarded as having a probably intimate connexion with the marked decline in the metropolitan mortality from this disease in the last ten years. It is satisfactory, therefore, to find that a still larger proportion of the cases is at the present time being treated in hospital. In the ten weeks ending last Saturday more than 30 per cent. of the deaths from scarlet fever in London occurred in the Metropolitan Asylums and London Fever hospitals; in the various groups of registration districts this proportion of hospital-treated cases of scarlet-fever ranged from 20 per cent. in the north and 23 per cent in the east, to 32 in the central and south, and 41 in the west. If we accept the proportion of cases of scarlet fever treated in hospital as affording any test of the efficiency of local sanitary organisation, it is not without interest to note that in the sanitary districts of South London this proportion has ranged in the past ten weeks from 7 per cent. in Bermondsey to 44 per cent. in St. George's, Southwark. It is evident that the continued increase in the proportion of hospital-treated cases of scarlet fever in London causes the hospital returns to give a somewhat exaggerated impression of the prevalence of scarlet fever in the metropolis. Moreover, there is good ground for believing that the type of the disease, which has recently showed such rapidly increased prevalence, is exceptionally mild, and that therefore the deaths from scarlet fever have not increased at anything like the same rate as the cases admitted to hospital.

MEDICAL JURISPRUDENCE IN ITALY.

A HOLIDAY contributor writes: "As Italy is getting nearer and nearer the goal of her ambition, to be a first-class Mediterranean power, she becomes, *pari passu*, more and more sensible of her deficiencies, and is continually measuring herself, in this department and in that, with her European rivals, generally (to her credit be it spoken) with a frank confession of inferiority, which is the first step towards substantial improvement. I have been struck with this wholesome sign on many quite recent occasions, and not least, on that of the controversy now occupying the Neapolitan journals as to her degeneracy in the teaching and still more in the practice of legal medicine. In this department she led the van, as in so many others, at the Renaissance; now she talks of herself as having fallen far below the standard of Germany and France. For a parallel, indeed, to her self-depreciation in 'medecina legale' we must go back to the Scotland of sixty years since, so graphically described by Sir Robert Christison in his Autobiography. In none of her medical schools, save perhaps three, is medical jurisprudence taught in such a way as to subserve the cause of justice before the national tribunals. Nothing but didactic prælection is meted out to the young medico-jurist, except in Pavia, in Padua, and in Naples, where something like practical training is to be witnessed. Even in these cases, notably in that of Naples, the Government has contributed nothing; the individual energy of the professors has done all. In her numerous criminal trials in which skilled medical experience is appealed to, the counsel for the defence invariably secures far better representation than the public prosecutor, whose choice (so say the leading journals of Naples) is greatly hampered by the miserable *honoraria* at his disposal for the professional skill he invokes. Confusion, contradiction, defeat of justice, too often mark the initial stages of the process, and when the representative of the Crown is driven to calling in superior experts, it is often too late to go over again the bungled and misused *indicia*. Imagine, says a correspondent of the *Piccolo*, a case of deadly poisoning in which the diagnosis was made without the stomach being opened and examined at the necropsy! But this has occurred, and is a typical example of the perfunctory character of expert evidence in the criminal trials of Italy. Payment of professional opinion by the State is almost incredible, both as to system and as to shabbiness. It is regulated *a norma del domicilio*—that is, if the physician or surgeon who is called in resides in what we should call a county town (*capoluogo*), where there is a civil or correctional tribunal, his fee is higher than if his residence is in a commune not similarly provided. Distance and the number of visits he has to make are also elements in graduating his *honorarium*. Thus, for every visit or report he makes, if residing in a county town, he gets three lire (2*s.* 6*d.*); if the town he resides in be not such, he gets two lire (1*s.* 8*d.*). Post-mortem examinations are also paid *a norma del*

Digitized by Google

domicilio, from six lire (5*s.*) to four lire (3*s.* 4*d.*) If the skilled expert is engaged more than four hours over an operation, he gets, in addition to the above, from two to three lire, *a norma del domicilio*, as before. The Italian Government, so say its critics, must raise the remuneration of its medico-legal officers to some equality with that accorded by the outside public, and concurrently it must do what private energy like that of Professor de Crecchio of Naples has done—endow the claims of legal medicine with the means of practical observation and research, so as to provide the student with opportunities of thorough training in his *métier*. Then, and not till then, will Italy resume her old place in legal medicine, and show herself worthy of her great physicians and jurists of the past—of Vico, of Romagnosi, of Beccaria, of Filangieri, and of Puccinotti."

REFLEXES IN NEWLY BORN CHILDREN.

DR. JULIUS FARAGÓ has published in the *Gyógyázat*, a Hungarian journal, some observations he has made in Professor Ebstein's clinic in Prague on the reflexes of newly born children. Advantage was taken of the lax state of the muscles of the lower extremities while the child was at the breast to test the patellar reflex. Altogether 117 infants under sixteen days old were examined. In all these the patellar reflex was present on both sides, but the strength of the jerk varied a good deal. In some cases there was merely a slight, short, sudden extension of the leg. In others the jerk was stronger and followed by a series of oscillations. Frequently a transient clonic contraction of the quadriceps was noticed. In some cases a slight contraction was observed in the quadriceps of the opposite leg. Dr. Faragó found that the knee reflex is stronger immediately after birth than during the second week. Premature and badly developed children, weighing less than 3000 grammes, have a weaker knee reflex than children born at term weighing more than 3000 grammes. The abdominal and eyelid reflexes were also noted. The cremaster reflex was present in all the forty-nine male children except nine, and in these the testicles were high or else hydrocele was present.

DUCKER PORTABLE HOSPITAL.

WE have had an opportunity of carefully inspecting, at the Wellington Barracks, a portable barrack constructed by the Ducker Portable Barrack Company at Brooklyn, N.Y., on the model of the one which gained the prize medal offered by H.M. the Empress of Germany. It is constructed in sections made of strong light wooden frames, covered outside and inside with a material called "leather-board," made of leather and jute. This is said to be fireproof, and is so strong as to be free from any risk of damage from accidental rough usage or intentional blows. The fact of there being about an inch of space between the outer and inner covering will tend greatly to prevent the heat or cold of the external air being so much felt as in ordinary wooden huts. The roof is made of the same material, and, like the walls, is double. The leather-board is waterproof, and the hut can therefore, when necessary, be thoroughly cleaned or disinfected by washing. Abundant means of ventilation are provided by a window between each bed, fitted, in addition to the glass sash, with a Venetian shutter, and by an arrangement, should it be deemed necessary, for leaving a space open along the ridge pole. At one end of the building is a small annexe for a stove, by which it may be sufficiently warmed, and at the other end a corresponding one for an earth-closet. The building we examined is adapted for twelve beds, but the Company make them of any size, from four beds upwards. The whole building can be quickly taken down and packed for removal on an ordinary waggon. It seems very well suited for use wherever a temporary quarter may be required, and might be advantageously employed as a hospital for infectious cases during an epidemic. The only defects which we noticed were the want of an ablution room, which could easily be added as an annexe, and used also as a bath-room, and the opening of the annexe for the earth-closet into the hut; it should at least be separated by a short ventilated passage. The building appears to possess all the qualities required to form a portable, useful quarter or hospital, easily put together, quickly taken to pieces, and safe from any serious damage in the transport. The cost of a twelve-bed hut, delivered in this country, is estimated at about £140.

A BELGIAN ON PROFESSIONAL OVERCROWDING.

A WRITER in *Le Scalpel* the chief Belgian provincial medical journal, has been endeavouring to suggest some satisfactory remedy for the yearly increasing overcrowding of the professions of medicine and pharmacy, each of which is not only far too full itself, but tends to jostle and compete with the other in an undignified manner, complaints and recriminations frequently making themselves heard in the various organs representing respectively medicine and pharmacy. "Legislation which would satisfy us," says the writer referred to, "might be summed up in a few words: 'Pharmacy for pharmacists, but medicine for doctors.'" Let the pharmacists have the sole right to sell medicines, and let drug shops be prohibited as both useless and dangerous: useless because pharmacists sell all the articles which druggists keep—at least those that are not readily obtained elsewhere; and dangerous because the druggist knows but little about poisons, to say nothing of the temptation under which he is to give medical advice to customers. Again, the writer desires that the privilege of keeping a pharmacy and dispensing their own medicines, which is now allowed to medical men in some parts of the country, should be abolished—not, of course, all at once, but gradually. In some poor and sparsely populated localities where there are no pharmacists, and where there is no living to be had for them, it is absolutely necessary for the doctors to dispense, as is the practice in this country; but in other places, where, since the permission to dispense was originally given, poor villages have developed into thriving little towns or important centres, there is not the same necessity for dispensing that formerly existed. Even here, however, it is admitted that it would be impracticable to make the change without long notice. A doctor would have to make his patients understand that he could not attend them for the same fees as when he dispensed, and, of course, charged for his medicines besides. There are many parts of the country where it would be impossible for both a doctor and a pharmacist to earn a living. If they attempted it, both would be in a wretched condition; and if the doctor should be driven away by want, the inhabitants would be left with only the pharmacist. The only solution of the difficulty is, of course, to allow the doctor to dispense, and in such cases the pharmacists have no real cause of complaint. Where hospitals are too small to keep up a dispensary under a pharmacist, the writer thinks that, except under special circumstances, the medical officers should not dispense, but that arrangements should be made with local pharmacists to do the necessary dispensing. He then discusses the question of free trade in pharmacy, and expresses himself in favour not merely of increased stringency in examinations, but of limiting the number of pharmacies, as in Germany. Limitation would, he thinks, serve to increase the scientific attainments of the pharmacists, and to diminish the temptation to sell drugs which are adulterated or of inferior quality. In reading

Digitized by Google

articles such as this, which are common enough in continental medical journals, two things strike us forcibly: firstly, the universality of the cry of overcrowding; and, secondly, the widespread nature of the belief that legislative interference of one kind or another will help men who are now, either from faults of their own or from force of circumstances, unsuccessful in obtaining a really good livelihood by the exercise of their profession. Whatever may be the case in foreign countries, it is quite certain that no British Parliament would listen for a moment to any suggestion limiting the number of medical men or chemists further than by obliging all to reach a moderate standard of competency.

SEA-BATHING AT EBB TIDE.

BATHING on an unfamiliar coast is, in any condition of the tide, a risky proceeding. The play of currents is so uncertain that the best swimmer even will be wise to fortify himself with the opinions of those acquainted with the shore and its phenomena before committing himself to the tidal wave. For non-swimmers the precaution is a matter of the most elementary prudence. It is often supposed that safety from all such perils may be assured by the simple expedient of bathing at low tide. Then it is argued, if any current should be set up, its flow will be towards the shore, so that to a bather in difficulties it will be a help rather than a source of danger. Often enough this expectation will be justified by the event, but this is by no means a matter of course. Attention has recently been publicly drawn to the obvious fact that the sea shore does not, as a rule, always slope with a continuous declivity out to sea. It often happens that at some point a gentle elevation or undulation of the surface of the ground will offer a shallow space surrounded on every side by deeper water, and cut off, it may be, by a belt of sea deeper by a foot or two than that in which an unwary bather may be taking his pleasure. In these circumstances an inflowing tide is a very serious matter, unless the bather can swim well enough to cross the deep water. For by its gradual rising the dip of the ground intervening between himself and *terra firma* may be submerged to beyond his depth long before the surging of the water about him warns him to seek the shallower parts. In such a case he will be fairly caught, and he is very fortunate if at the moment of his need he can summon efficient help. It is foolhardy for any person to bathe at sea beyond the visible reach of aid, but upon those who are inexperienced in distance swimming the necessity of taking every possible precaution cannot be too strongly or too constantly enforced.

THE CHEMICAL TEST FOR KOCH'S BACILLUS.

THE diagnostic value of Koch's cholera bacillus having been considerably impaired by the proved existence of other micro-organisms of like morphological characters, the discovery by Pohl, Brieger, and others of a chemical reaction alleged to be peculiar to cultures of the comma bacillus was welcomed as an additional test of importance. This reaction consists in the development of a red colour (*cholera-roth*) on the addition of hydrochloric acid to the cultures, and, as Brieger has shown, the colour depends upon the presence of a ptomaine containing derivatives of indol. We now learn from the experiments of Ali-Cohen, of the Hygienic Institute of Groningen (*Fortschritte der Medicin*, No. 17), that the reaction is not peculiar to the comma bacillus, and that it may be obtained by the use of any mineral acid that contains the impurity of nitrous acid, for the pure acids do not produce it. The indol derivative is produced by Koch's bacillus somewhat more rapidly than it is by other morphologically identical forms; but then there are bacteria not morphologically allied to the comma bacillus which can produce this substance quite as readily. The discovery of the *cholera-roth* is thus shorn of its diagnostic value, and reliance must still be placed upon bacteriological methods for differentiating the cholera-organism.

THE LONDON WATER SUPPLY.

IN submitting to the Water Examiner appointed under the Metropolis Water Act, 1871, the results of their analyses of 182 samples of water collected by them during July last from the mains of the seven London water companies taking their supplies from the Thames and the Lea, Messrs. Crookes, Odling, and Tidy remark:—"The water supply of the past month was characterised by an appreciable diminution in the habitually small proportion of organic matter present. In the case of the companies taking their supply from the Thames, the mean amount of organic carbon was 0·146 part, and the maximum in any one sample 0·169 part, in 100,000 parts of the water, corresponding respectively to about one quarter of a grain, and to about three-tenths of a grain of organic matter per gallon. More marked even than the diminution in its proportion of organic matter was the increased degree of freedom of the water from other than a bluish tint of colour. The slight turbidity manifest occasionally for some months past in the East London Company's water was noticeable during the past month, and that to a very insignificant extent, in two samples only."

SCARLET FEVER AT WOLVERHAMPTON AND IN THE PROVINCES.

SCARLET FEVER is rapidly extending in Wolverhampton. Fifty cases have already occurred, and the disease is spreading amongst school children and others. In the local press a hope is expressed that with the cool weather a diminution of the epidemic may be expected. Unfortunately this is the reverse of what may be anticipated to occur. Scarlet fever generally tends to increase both in extent and fatality during the closing months of the year; and it is this contingency that the sanitary authority is most likely to have to face. Unfortunately scarlet fever epidemics are occurring in several parts of the provinces, and there are reasons for fearing that the marked diminution in the death-rate from this disease in England and Wales, which has been noticeable for some years past, has come to an end, and that with a large child population unprotected by former attacks a general recrudescence of the disease may be expected.

AN INJUDICIOUS JURYMAN.

SOME lawyers, careful only for the speedy transaction of business, have condemned as opposing an unnecessary obstacle to the course of justice the system of trial by jury. Some jurymen, on the other hand, have shown at times an undue sense of the dignity and responsibility of their office by the tenacity with which they have maintained, in season and out of season, their privilege of individual judgment. Of this number was one who officiated at an inquest held a few days ago on the body of a man who died suddenly of apoplexy. Having tried in vain to obtain from the medical witness in this case an answer to the question whether the death of the deceased was positively attributable to the paralytic seizure, or to the fact that he had previously had a fall, he commented in an excited manner on what he considered to be culpable ignorance on the part of the practitioner. We do not blame him for the inquiry. It was not an unnatural one, nor was it inappropriate to the purpose of the inquest. What we do condemn, as the coroner also did, is his pertinacious insistence that here doubt was inexcusable and tantamount to incapacity. Questions of this kind, it is true, are sometimes capable of

Digitized by Google

more definite solution, but as often they are not so, and it certainly argues neither ignorance nor negligence in examination when, in the latter case, a medical man is unable to make a cut-and-dried statement assuming an impossible certainty. It seems very clear that had the obstructive member at this inquest observed a due regard for this fact, time would have been saved, needless friction avoided, and justice satisfied.

EXTENSIVE CONTRACTION OF THE LARGE VESSELS.

PROFESSOR C. WALLIS of Stockholm reports an interesting case of stricture or contraction of the large vessels. The patient was a girl of thirteen, who was admitted into hospital with chronic nephritis and hypertrophy of the heart. She died suddenly after having left the hospital, where she had been fairly well. She went home on foot, a walk of about twenty minutes. Before her death she suffered from violent choking sensations. At the post-mortem examination the heart was found to be enormously hypertrophied—as large, indeed, as that of a man. There were no valvular lesions, but there was a marked narrowing of almost the whole of the aorta and of the pulmonary vein; that of the aorta, which was the more marked of the two, was continued into its principal branches, and attained its greatest degree in the abdominal aorta, where a thrombus was found which entirely occluded the vessel. The narrowing was due to chronic arteritis affecting all the arteries to a variable extent. This arteritis consisted principally of cellular infiltration, but also partly in the formation of a firm cellular tissue. No calcareous deposits were found. Professor Wallis is not able to speak positively as to the cause of the affection, but he is disposed to consider it as probably of syphilitic origin on account of the amyloid degeneration which was present in the liver, for which no other cause, as tuberculosis or malaria, appeared to exist. It is, however, right to say that no confirmatory evidence of the existence of a specific taint could be made out

FIRE-PROOF FABRICS.

IT has long been known that all fabrics, even the most delicate gauzes and muslins, may be rendered uninflammable by chemical treatment. Of course they cannot be made incombustible, but they can easily be so prepared as to be incapable of bursting into flame. The chemical agents employed act by checking and modifying the destructive distillation which precedes what is properly known as inflammation. A familiar example is afforded by phosphorus. Although phosphorus is itself very inflammable, it is difficult to light wood or paper from its flame, because the solid phosphoric acid formed in the combustion coats and protects the article presented to it. Phosphorus burnt on paper chars but rarely ignites it. The chemicals most commonly used for the purpose are alum, borax, phosphate of soda, sal-ammoniac, and tungstate of soda. Alum acts injuriously on the fabrics, especially if coloured, but the others are commonly harmless, and most of them are cheap. Tungstate of soda is the best. Used singly, it is apt to become insoluble and to rub off, but this risk can be diminished by the addition of about 3 per cent. of phosphate of soda. After the ordinary washing, the goods should be immersed before wringing and drying in a solution containing 20 per cent. of tungstate with a proportionate quantity of phosphate. In view of the recent terrible disaster and of many preceding ones, it would surely not be too much to insist that all dresses, hangings, side scenes, and the like, worn or used on the stage, should be protected by this or by some other suitable material. Fires almost always begin on the stage or near it, and no one who has been behind the scenes before or during a performance can wonder at it. It is not too much to say that there is always an imminent risk of fire, and every cause which can lead to it should as far as possible be removed. Of course other reforms are necessary, especially means for the prevention of panic such as we insisted on last week—electric lighting, the fireproof curtain, the smoke exit, the fireman always ready with his hose, and greater facilities for escape. But if any or all of these were adopted and insisted on, it would still be most desirable that as many as possible of the articles which commonly lead to the disasters should be rendered fire-proof. It is matter for grave regret that the Government decided to take no action until next session of Parliament. It would doubtless have been impossible to pass a Bill, but a Royal Commission might and ought to have been appointed to consider and report on the best means of averting horrors which dismay the whole country. We all know how soon public interest in such matters subsides, and unless something is done at once it is greatly to be feared that the old and vicious system will be allowed to continue indefinitely.

HEALTH OF CALCUTTA.

THE return of the health officer of Calcutta for the second quarter of the year shows the deaths to have amounted to 2463, which exceeds the number in the same quarter of 1886 by 220, but is lower than in any other year of the decennium except 1880. The deaths from fever amounted to 679, and from cholera to 438. The death-rate of the quarter was in the annual ratio of 22·84 for Calcutta and 39·21 for the suburbs per 1000 of the population—a difference dependent, no doubt, in a great measure upon the very insanitary condition of the latter. We learn with much regret that the sanitary staff, which in November last, on the recommendation of the health officer, was organised for the systematic inspection of localities and premises, has been dismissed by the commissioners. We cannot but foresee that disastrous consequences are likely to occur from such a proceeding on the next outbreak of an epidemic of cholera. This miserable economy, if it deserve such a name, of keeping down the rates at the expense of the public health, shows how unfit the natives of Calcutta are for self-government.

CORTICAL BLEPHAROPTOSIS.

THE region of the angular gyrus, according to Grasset and Landouzy, contains a centre for the raising of the upper eyelid of the opposite eye, since crossed blepharoptosis has been observed as the result lesions of the pli courbe. M. Lemoine has discovered an old focus of softening in the left pli courbe of a man who during life suffered from mitral stenosis, and was attacked four years before his death with an apoplectiform seizure and sudden ptosis of the right eye. It is doubtful, however, whether there is any very special relation between this cortical visual region and movements of the upper eyelid, since ptosis has been found in many cases in which this region was not obviously involved.

A PROVIDENT HOSPITAL.

ACCORDING to the *Citizen*, it is proposed to convert the title of the Metropolitan Free Hospital into the "Metropolitan Provident Hospital." The working of the institution is to be limited to the radius of a mile from the hospital. The district is to be divided into some half-dozen sections, each with an office presided over by a secretary, who would receive the payments. The tariff of payments would be 4*d.* for each adult, 2*d.* for each child; accidents are to be treated free, and advice and medicines to be given to the members of the Society. This scheme does not excite our admiration. It will apparently turn a hospital into a great

Digitized by Google

provident dispensary. We do not wonder that there is dissatisfaction among the working men with this scheme. It degrades a hospital for all needy sick into a provident dispensary with territorial and money limitations of the narrowest order. And it is not likely to please medical men, who do not need the competition of a hospital for the small pittances which the poor have to give in the shape of medical fees.

MEDICAL ARRANGEMENTS AT THE BELGIAN MANŒUVRES.

THERE have recently been some autumn manœuvres in Belgium, the military medical service being organised this year for the first time in connexion with the manœuvres. The surgeons, pharmacists, and other officers were furnished with a little book of instructions. In the field each army corps had four ambulance columns and four field hospitals, each of the latter comprising a pharmacy waggon, an administration waggon, and an ambulance waggon, with four surgeons, two pharmacists, forty-two men, and twenty-two horses, also a depôt of hospital furniture and reserve stores. When a division was engaged, it had eight surgeons and seventeen pupil surgeons at the front, five surgeons and four pupil surgeons at certain posts, with twelve *infirmiers*, also five surgeons at the dressing station with the ambulance column. The directions given to surgeons at the front under fire were: Hæmorrhage to be stopped by temporary expedients; limbs already nearly separated from the body by projectiles to be removed; a penetrating wound of the abdomen or thorax to be closed; a fractured limb to be fixed. No other operations to be performed under fire. Wounded who fall in a state of syncope not to be brought to. The bearers to assist enemies and friends alike, beginning with those most seriously hurt.

THE SANITARY STATE OF YORK.

THE maintained prevalence of typhoid fever in York is a matter of serious importance. With one exception, there was no single week from Jan. 1st to Aug. 27th of this year in which fresh attacks of this disease were not notified, and in the last week referred to the number was as high as 18. We learn from another part of Mr. North's report that careful inquiry is made into each case, and that much sanitary work and the removal of filth and foul and offensive accumulations are the result. But we have yet to learn that the Town Council have determined on the abolition of the system which allows the storage of large quantities of excreta and refuse near houses—a matter which is of paramount importance in view of the altogether unnecessary spread, from time to time, of typhoid fever in the city. The drainage question in Holgate is also pressing; but it has been "for the present deferred" until the whole question of the drainage of the entire city has been fully discussed and some decision arrived at.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Michael J. Dietl, formerly Professor of General and Experimental Pathology in the University of Innsbrück, from cardiac disease, which obliged him to give up his professorship some years ago. He died at Marienbad, and was only thirty-nine years of age.—Dr. Brehme, *Medicinalrath* of Weimar.—Dr. Friederich Reissner, *Obermedicinalrath* of Darmstadt, whose name is known in connexion with a method of preserving animal lymph.—Dr. Johannes Skalweit, of Hanover, for many years secretary to the Society of Analysts and editor of the *Repertorium für Analytischer Chemie*.—Dr. Schott, Professor of Pathological Anatomy in the University of Innsbrück, of heart disease and nephritis, at the age of fifty-seven.

CONGRESS AT AMSTERDAM.

THERE is to be a Congress for the discussion of Natural Science and Medicine at Amsterdam on the 30th of September and the 18th of October. There will be four sections—1. Physics and Chemistry, under the presidency of Professor Vandesande-Buckhuyzen. 2. Natural History and Biology; president, Professor T. W. Engelman. 3. Medicine; president, Professor Donders. 4. Geology and Geography; presidents, Professors Martin and Kan. This is to be essentially a Dutch Congress, but invitations have been sent to scientists and medical men belonging to the Flemish parts of Belgium. These have, it seems, up to the present time returned but little response to the invitation, only six Belgians having as yet expressed a desire to take part in the Congress, though no less than 500 Dutch members have already enrolled their names. Abstracts of the papers read will be published without delay.

MEDICAL REGISTRATION.

OUR advertising columns this week contain an announcement from the Registrar of the General Medical Council which we hope will not escape the notice of the profession generally. Much inconvenience has occasionally been experienced by the neglect to send to the Branch Registrar by whom the registration was originally effected notice of change of address, in order that such may be entered in the Register; or to reply to any letter of inquiry that may have been sent from the office. It should be remembered that failure on the part of a registered medical practitioner to comply with the requirements referred to involves the liability of having his name removed from the Register. Also notice should be sent to the same Branch Registrar of any additional qualification it is desired to append to a name on the Register.

DISINFECTANTS IN MADRID.

THE Madrid municipality has arranged to provide and to pay for disinfectants for employment in streets and houses when their advisers consider them necessary. This, as the leading Spanish medical journal points out, is a very unsatisfactory sanitary precaution, because these substances, to be of any real use, ought to be at hand at a moment's notice, which of course they will not be; but what is more important still, they cannot be of much service as long as cleanliness is so terribly neglected. It would have been much better had the municipal authorities set themselves earnestly about cleansing thoroughly all public places, and insisting on private persons using equally vigorous measures with regard to localities and houses under their control.

HABITUAL DRUNKARDS.

THE seventh report on the working of the Habitual Drunkards Act, passed in 1879, is now published. It is not a great record, for the Act itself was a poor, feeble piece of legislation, which assumes in habitual drunkards a power of resolution and a reserve of self-respect which are conspicuous by their obliteration. To show how ineffective the Act is, only seventy-three persons last year entered the five or six retreats created under the Act. It is gratifying to learn that in a large proportion of the cases actually treated good results have been obtained. The inspector, Mr. Hoffman, says he is "of opinion that very few are hopeless cases, if they will only give themselves time." The time requisite in most cases is twelve months. We agree with Mr. Hoffman that there is great hope for drunkards, even female drunkards, if law and society would give them fair play and a little help. But to expect them *voluntarily* to agree to part for twelve months from that which they morbidly and madly love is

Digitized by Google

to be unpractical, and to embody such an expectation in a statute is to display the impotence of legislation. Habitual drunkards are now practically at liberty to go on to their own destruction and that of their families, whose life is often one of extreme misery.

SMALL-POX AT ROTHERHAM.

SMALL-POX has for some time past been prevalent in Sheffield, and it is now extending to adjoining townships. Rotherham is one of the places infected, and it appears also to be one of those districts where no proper arrangements have been made for the isolation of first attacks of infectious disease, and where, in consequence, such an emergency as a small-pox prevalence finds the proper guardians of the public health at a loss to know how to perform their duty. In this difficulty they have turned to the guardians of the poor, but this body has neither the means nor the legal right to undertake the duty of aiding them. It is sincerely to be hoped that no such emergency hospital will be devised as will prevent the erection of a proper hospital at a time when the requirements of the district can be thought out uninfluenced by panic, the result of previous failure to perform an obvious duty.

A RIVAL TO COCAINE?

AN alleged alkaloid named stenocarpine, which Dr. Claiborne of New York has extracted from the leaves of a yet unidentified tree having a close resemblance to acacia stenocarpia, is said to possess anæsthetic properties of so pronounced a kind as to make it not improbable that stenocarpine will prove a formidable rival to cocaine. From two to four drops of a 2 per cent. solution instilled into the conjunctival sac enabled various painful operations to be performed on the eye. This dose of the solution of the alkaloid caused complete anæsthesia of the cornea and conjunctiva, lasting twenty minutes. Like cocaine, stenocarpine is mydriatic and causes a lowering of the intra-ocular tension. The anæsthetic effect can also to obtained on the nasal mucous membrane.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The two assistants in the first medical clinic having been promoted to professorships, the winter session will see two fresh aspirants for professorial honours in their places, Staff-Surgeon Dr. Renvers and Dr. Klemperer.

Catania.—Dr. Musumeci has been appointed *privat docent* of Medical Pathology.

Genoa.—Dr. Giura has been appointed *privat docent* of Descriptive Anatomy, and Dr. Bossi *privat docent* of Obstetrics and Gynæcology.

Innsbrück. — Dr. Moritz Loew, of Prague, has been appointed Extraordinary Professor of General and Experimental Pathology.

Leipzig.—Dr. W. Ostwald, of Riga, has been appointed Professor of Chemistry and Director of the second Chemical Institute.

Naples.—Dr. Paolis has been appointed *privat docent* of Obstetrics and Gynæcology.

Palermo.—Dr. Scimenni has been appointed *privat docent* of Ophthalmology.

Parma.—Dr. Pacinotti has been appointed *privat docent* of Clinical Surgery and Operations.

Pavia.—Dr. Orsi, Professor of Pathology and Clinical Medicine, who has been absent on account of ill-health, is about to resume his duties.

As we intimated last week to be a likely occurrence, the Emperor of Austria has conferred on M. Pasteur the decoration of the Iron Crown, which includes the title of Baron.

DR. G. F. BURDER, in a letter to the *Western Daily Press*, states that the drought experienced in England this summer has been paralleled in intensity only twice within the last thirty-five years—namely, in 1864 and 1870. In the former year the total rainfall from Jan. 1st to Aug. 29th was 12·172 in.; in the latter during the corresponding period it was 11·655 in.; whilst in the present year it was 12·813 in. Excluding the first two days of June and the last two of August, the rainfall amounted in those three summer months to but 2·385 in.

MILAN is about to erect a bronze statue to Dr. Agostino Bertani, Surgeon-in-Chief to Garibaldi's expeditionary corps in the Italian wars of independence. The sculptor (Vela, of the canton Ticino) has succeeded admirably, and his work will be unveiled with much ceremony on the anniversary of the defence of the city against the Austrians, known as "the five days."

AN original drama, entitled "Black Mail," written by Dr. G. H. R. Dabbs, was played at the Assembly Rooms, Shanklin, I. W., on the 1st inst., with considerable *éclat*. The principal character, "Squire Meredith," was sustained by the author. There are several good medical points in the play.

A WORK by Dr. Charles Mercier treating of the functions of the brain and nervous system, and intended to serve as an introduction to the scientific study of insanity, will shortly be issued by Messrs. Macmillan. It will contain an exposition of the new neurology, and an account of the constitution of mind from the evolutionary standpoint.

IN Aberdare valley the cases of enteric fever are very numerous, the number given last week being 211, with 13 deaths. Typhus has broken out at Dowlais, and is said to have been traced to a dirty, overcrowded dwelling, where rags were used for bedding.

DR. NATHANIEL ARCHER RANDOLPH, Professor of Hygiene in the University of Pennsylvania, met his death by drowning on August 21st. The deceased physician was joint editor with Dr. C. W. Dulles of the *Medical and Surgical Reporter*.

HEALTH OF THE ARMY.

No. I.

THE Army Medical Department Report for the year 1885 shows the average strength of the troops at home and abroad, exclusive of colonial corps, to have been 177,928 warrant officers, non-commissioned officers, and men. The admissions into hospital were in the proportion of 1131, the deaths of 11·12, the discharges by invaliding of 19·79, and the mean daily sick of 57·86 per 1000 of the strength. These ratios are all higher than in the preceding year, and the admissions and mean sick are also above the average of the last ten years. The increase has been general throughout the commands, only Canada, Bermuda, and Ceylon having shown a decrease in the admissions, and the West Indies, Mauritius, and Ceylon, in the deaths, compared with the proportion in 1884. The greatest increase in the death-rate occurred in Egypt, Malta, Cyprus, China, and Gibraltar.

In the United Kingdom, an average force of 87,105 furnished 877 admissions, 6·68 deaths, 21·61 discharges by invaliding, and 48·46 constantly non-effective from sickness per 1000 of strength. With the exception of the mean sick, these ratios are slightly above those of 1884, but the difference is not greater in any of them than might be accounted for by the ordinary fluctuations in limited numbers, and they may be considered as indicating a satisfactory state of

Digitized by Google

health. There were 19 cases, with 3 deaths of small-pox; of these, 5 and 1 death occurred at Enniskillen; 4, with 2 deaths, at London and Hounslow; 3 at Colchester, believed to have been imported from London; and the remainder at different stations in England. There were 96 cases of scarlet fever admitted, of which 3 died; they occurred at stations widely spread over the country —London, Dublin, Fermoy, and Templemore furnishing the greatest number; the Channel Islands, Woolwich, and Aldershot were exempt from it. Of measles, 128 cases were returned, Woolwich and Dublin being the stations most affected. Enteric fever shows a considerable increase; the cases amounted to 146, and the deaths to 42, or 2 in 7 cases; the increase is stated to have been "chiefly due to the occurrence of cases in men recently returned from service in Egypt," but the details given in the report do not enable us to estimate to what extent this circumstance contributed. Chatham and the Channel Islands appear to have been the only military districts which were free from the disease. The only instances in which local insanitary conditions are reported as the cause were—of 1 case in Hyde Park Barracks, "believed to be dependent on a drain which had been opened"; of 3 cases at Pontefract, which "were possibly connected with the faulty condition of a sewer"; and of 1 at Chester, "attributable to faulty drainage." London had the greatest number of cases, amounting to 38, but with only 5 deaths. Of 8 cases of diphtheria, with 2 deaths, 4 occurred at Aldershot, with 1 death, "no doubt influenced by the nature of the soil and the (then) defective drainage of the South Camp, where most of the cases occurred. Improvements in the drainage system have since been effected." Syphilis continues to furnish the high ratio of admissions which followed the abolition of the Contagious Diseases Acts. It amounted in 1885 to 154 per 1000. "Considerable variations in the ratios of prevalence of syphilitic affections are observed in the different districts. Primary syphilis ranges from 189·8 per 1000 in the Dublin district to 51·2 per 1000 in the Cork district. Among the districts showing high rates of prevalence are the Channel Islands 175·7 per 1000, Aldershot 174·2, Home 172·6, and Chatham 135·8 per 1000; and among the districts having comparatively low rates of prevalence are the North British 94·6, the Western district 98·0, and the Southern district 99·5 per 1000.....Including gonorrhœa and its sequelæ, the ratio of admissions for all forms of venereal disease was 275·4 per 1000.....The rate of constant inefficiency from these affections was 19·34 per 1000....." Of 43 deaths returned under the class of general injuries, 34 were by drowning, of which 4 were suicidal and 30 accidental. The total number of suicides was 30, or double that of the previous year. The admissions into hospital from the different arms of the service ranged between 729 per 1000 from the Royal Engineers and 1149 from the Foot Guards; the deaths, between 2·36 in the Household Cavalry and 11·06 in the Royal Engineers; the discharges by invaliding, between 18·96 from the Infantry of the Line and 31·85 from the Foot Guards; and the mean daily sick, between 32 in the regimental depôts and 69 in the Foot Guards. The cause of the latter very high ratio appears to call for inquiry, no explanation of it being given in the report.

In an average strength of 3160 officers, the cases of illness amounted to 292 and the deaths to 7·60 per 1000. Three deaths out of a total of 24 were due to a shell explosion at Shoeburyness; diseases of the circulatory system were the most fatal, being the cause of 5 deaths, 2 from valvular disease of the heart and 3 from aneurysm.

The cases of sickness among the women were in the ratio of 377 and the deaths of 7·59 per 1000. Among the children, the cases were 449 and the deaths 25·57 per 1000. Twenty-eight cases of diphtheria were reported, of which 5 died; 17 of the cases and 1 death occurred at Aldershot.

The reports of the Principal Medical Officers of Districts show that a careful supervision of the sanitary condition of the various barracks has been exercised, and that defects, when pointed out, have been remedied as far as possible.

The average strength of the garrison of Gibraltar was 4383. The admissions into hospital from it were 1034 per 1000; the deaths 8·04; the invaliding 39·28; and the constantly sick 58·25. These ratios are all higher than those of the preceding year, and also above the decennial average. The excess in the admissions was chiefly due to syphilis and gonorrhœa, which were 71 per 1000 higher than in 1884, and there was also an increase in the cases of rheumatism; that of the deaths was from the occurrence of 2 fatal cases of cholera and 3 of enteritis, which bore a close resemblance to cholera, but of which Surgeon-Major Troup reports that the symptoms "simulated cholera, but the characteristic and diagnostic rice-water stools were absent. The origin was traced to the partaking of fish improperly prepared, to a mixture of grapes, alcoholic drinks, and excessive water drinking, with, in one case, sea-bathing subsequently." The cases of cholera could not be traced to any local cause. The disease was prevalent at the time in the neighbouring village of Linea, and cases had occurred among the civil population of Gibraltar. There were 25 admissions and 5 deaths by enteric fever, being in the ratio of 5·7 and 1·15 per 1000. The cases came from all barracks, and the disease could not be traced to any defects in the barracks or their vicinity, or in the water supply. The deaths from injuries amounted to 1·38 per 1000 of the strength, or nearly double the average proportion.

At Malta, in a strength of 4602, the admissions were in the ratio of 923, the deaths of 14·77, the invalided to England of 26·94, and the constantly sick of 59·11 per 1000. With the exception of the invalided, these are all higher than in 1884, and also above the decennial average. The increase in the admissions has been chiefly in fevers, and, to a considerably less extent, also in diseases of the digestive system and in gonorrhœa; in the deaths it has been in fevers and tubercular diseases. The 1st Devonshire Regiment furnished the highest ratio of admissions, which was attributed by the principal medical officer "to the inferior physique and great youth of the men, which rendered them quite unable to endure the unusual heat of the past summer"; it had, however, the lowest death-rate of all the corps which were in the island during the summer, except the Royal Artillery. The only other corps which had as low a death-rate was the 1st Battalion Gordon Highlanders, which did not arrive till Sept. 12th. The cases of enteric fever amounted to 20·3 per 1000, or exactly the same as in 1884; but the deaths were 5·22, as against 4·74. Of the cases, 14 with 6 deaths occurred at Valetta, and 74 with 15 deaths at Cottonera, but we are not informed of the relative strength of the troops in each. The Principal Medical Officer attributes the difference to "the improved water supply of Valetta, while that of Cottonera remains much the same as before." Of remittent fever 72 cases were admitted, of which 3 died; they were of the form known as Maltese fever. "Antipyrin in thirty-grain doses is mentioned as being most efficacious in reducing temperature and affording relief to the headache and restlessness so much complained of." Syphilis was slightly less prevalent than in 1884, but almost identical with the rate of the last six years. There were 40 cases of dysentery with 2 deaths, but they almost all occurred in soldiers recently returned from Egypt. None of the other diseases seem to require notice.

The Royal Malta Fencible Artillery, 353 strong, furnished 821 admissions, 2·83 deaths, 11·33 invalids, and 26·60 constantly sick per 1000 of strength. The admissions and mean sick are above the average of preceding years, chiefly from the prevalence of fever and rheumatism, but the deaths and invaliding are under the average. The numbers under observation are, however, too limited to justify any deductions.

The average strength of the troops at Cyprus was 852; the admissions into hospital were 1077, the deaths 21·13, the invalided to England 8·21, and the constantly sick 43·60 per 1000. Except the invalided, these ratios are all higher than in 1884, and are also above the average of the preceding six years. The increase in the sickness and mortality was due to the arrival in July of 3020 officers, non-commissioned officers, and men from Egypt, many of the men "being in a very sickly and debilitated condition from the hardships of the recent campaign at Suakin, and to enteric fever having broken out among them." They were encamped at Troodos; three battalions of Guards left for England on August 25th, and the remainder of the troops from Egypt on Nov. 14th. Enteric fever caused 51 admissions and 15 deaths, being in the annual ratio of 59·8 and 17·61 per 1000. The only other deaths during the year were 2 of aneurysm and 1 of dysentery.

The troops serving in the Dominion of Canada are all quartered at Halifax; their average strength during the year was 1273. The admissions into hospital amounted to 715, the deaths to 7·86, the invaliding to 26·71, and the mean daily sick to 41·0 per 1000. The admissions and mean sick were lower than in 1884, but, except the admissions, all the ratios were somewhat higher than the average of the pre-

Digitized by Google

ceding ten years. Only one case of enteric fever occurred, which, however, terminated fatally. There was nothing noteworthy in the prevalence of the various classes of diseases. The quarters appear to be kept in a satisfactory sanitary condition.

The average strength of the garrison of Bermuda was 1335. The ratio of admissions into hospital was 494; of deaths 13·00, of invalided 23·83, and of constantly sick 28·04 per 1000. The deaths and invaliding were above, but the admissions and mean sick considerably under, the average. The reduction in the admissions was most marked in the diseases of the digestive and cutaneous systems and in local injuries. The excess of deaths was chiefly caused by enteric fever, and to a less extent by tubercular diseases. The admissions by enteric fever amounted to 20·9 and the deaths to 7·22 per 1000 of strength, the former being much lower and the latter a little higher than in 1884. Of the cases, 27 occurred at Prospect; the Principal Medical Officer was of opinion that their origin could be traced to milk supply, aerated drinks, and impure water furnished from outside military precincts, but the medical officer in charge at Prospect says that "sufficient evidence can be brought forward to produce a strong suspicion that the general insanitary state of the town of Hamilton is the cause, under favourable meteorological conditions." Of the prevalence of phthisis the Principal Medical Officer remarks that "phthisis does not seem indigenous in Bermuda, but if the disease is either inherited or imported, it develops with singular rapidity." The deaths from this disease amounted to 2·17, and the invaliding to 5·78 per 1000 of strength.

In the West Indies, the white troops consisted of two batteries of artillery, and the 1st Battalion, North Staffordshire Regiment, with detachments of Royal Engineers and garrison staff, divided between Jamaica, Barbadoes, and Trinidad. The average strength was 900, the admissions were 922, the deaths 7·77, the invalids 18·88, and the mean sick 43·08 per 1000. The admissions and mean sick were higher than in the preceding year, but the deaths and invaliding much lower, and they were likewise much under the average of preceding years. There were 3 cases and 2 deaths of enteric fever, 2 and a death at Jamaica, and the other fatal case at Barbadoes. Five cases of yellow fever, with 2 deaths, occurred in Jamaica; 4, including the two fatal cases, at Port Royal; and the other case at Newcastle. The disease is stated to have been epidemic during the last quarter of the year. On the occurrence of the 4 cases at Port Royal, 2 of which were men attending upon the first cases, the garrison was removed to a camp of isolation at Papine, and the progress of the disease was arrested. The case at Newcastle is stated not to have been contracted at that station. Syphilis and gonorrhœa were the chief causes of the increase in the admissions.

The average strength of the black troops was 1186; the admissions were 983, the deaths 15·17, the discharges by invaliding 22·76, and the mean sick 60·21 per 1000. Except the mean sick, these are all under the ratios of the last ten years, but the admissions and deaths are higher than in 1884. There was nothing in the distribution or occurrence of the diseases which seems to call for special notice. A reduction in the deaths by phthisis was counterbalanced by an increase in those by pneumonia. No cases of yellow fever occurred among the black troops.

In an average force of 422 black troops in West Africa the admissions were in the ratio of 1310, the deaths of 14·22, the invaliding of 59·24, and the mean sick of 69·03 per 1000. The admissions and deaths are under the average, though the former are rather higher than in 1884. Phthisis was, as usual, the cause of the greatest mortality. Three cases and one death of beri-beri were recorded.

At the Cape of Good Hope the average strength of the troops, including a detachment of 140 men at St. Helena, was 3939. The admissions were in the ratio of 881, the deaths of 8·89, the invaliding of 40·11, and the constantly sick, of 52·14 per 1000—all higher than in 1884. The increase in the admissions was chiefly from syphilis and gonorrhœa. There was also a moderate increase in paroxysmal fevers, due to the arrival of troops from Mauritius and Singapore. The greater prevalence of syphilis was most marked at Cape Town and Pietermaritzburg. Enteric fever was the cause of 7·4 admissions and 2·29 deaths per 1000 of strength. The greatest number of cases occurred at Pietermaritzburg, Cape Town, and Rorke's Drift. At Pietermaritzburg the disease was believed to have been caused by water which a detachment from Etshowe drank on the march. At Rorke's Drift it was probably also a consequence of contaminated water supply. At Cape Town three of the cases were believed to have been contracted at Kimberley or Barkly West, and four "in the poorer parts of the town where the disease is almost constantly present." At Rorke's Drift the removal of the troops to higher ground appears to have assisted in checking the disease. It is stated that throughout the colony at the military stations the dry-earth system of conservancy has been carried out with satisfactory results. The health of the detachment at St. Helena has been excellent.

The average strength of the troops on the Island of Mauritius was only 358. The admissions were in the proportion of 2508, the deaths of 16·76, the invalids sent home 39·10, and the constantly sick 82·43 per 1000 of strength. The admissions were higher, but all the other ratios lower, than in 1884. The admissions and mean sick were above, but the deaths and invaliding under, the average of the last ten years. The admissions by paroxysmal fevers continue very high, having amounted to 1478 per 1000, or nearly three-fifths of the whole. Of the 6 deaths which occurred, 2 were returned under the head of enteric and 3 of remittent fever, and 1 of dysentery. The accommodation at Curepipe was greatly increased, and the troops, with the exception of a small detachment, were removed from Port Louis. It is to be hoped that this change, combined with the improvements in the drainage at Curepipe, will result in a marked reduction in the prevalence of fever in the command. Two cases of enteric fever occurred—one at Port Louis and the other at Curepipe, both of which terminated fatally. "It is stated that they were of a typho-malarial character, and that it was impossible to trace their origin to any definite source."

In Ceylon the force averaged 809. The admissions were 1174, the deaths 9·89, the invalided home 29·66, and the mean daily sick 63·20 per 1000. These were all lower than in 1884, and also under the average of the preceding six years. Compared with the latter, there was a considerable increase in paroxysmal fevers, syphilis, and gonorrhœa, and in diseases of the cutaneous system, but a marked decrease in those of the respiratory, digestive, and absorbent systems, and in injuries. There was one fatal case of enteric fever; its origin could not be traced, but the disease is of frequent occurrence among the civil population throughout the island "owing to defective water supply." Four out of a total of seven deaths were caused by diseases of the digestive system, three of hepatitis and abscess of the liver, and one of enteritis. There were 6 cases of delirium tremens and 6 of alcoholic poisoning, being together in the ratio of 14·8 per 1000 of the strength, the direct result of intemperance. Steps are being taken to improve the water supply in the barracks at Colombo, and a grant of money has been sanctioned for the filling in of the moat, which is in a very unsatisfactory state.

The average strength of the troops in China and the Straits Settlements was 2188; the ratio of admissions was 1122, of deaths 11·43, of invalided 40·22, and of constantly sick 42·95 per 1000. Except the mean sick, these are somewhat above the average of the preceding six years. The force was nearly equally divided between Hong-Kong and the Straits Settlements; the admissions in the latter were considerably higher than at Hong-Kong, but the deaths less than half the ratio. Three cases of enteric fever with one death occurred at Singapore, and one case at Hong-Kong; those at Singapore are stated to have been contracted before arrival at the station. There were also three cases of typhus with one death at Tanglin, due, in the opinion of the medical officer in charge, "to overcrowding, which at that time existed in certain barracks and a temporary guard-room." Thirty-four cases of remittent fever with one death occurred at Hong-Kong; "it was supposed that the cause of the outbreak was the malarial exhalations from the rotten disintegrated granite of which the soil of Hong-Kong is composed," which had been freshly turned up around a newly erected fort. Cholera prevailed in an epidemic form among the troops at Hong-Kong from June 18th till July 19th. Nineteen cases occurred, of which 12 died, being in the ratio of 17·05 and 10·77 of the strength of the garrison. The troops were placed under canvas first at Kowloon, across the harbour, and subsequently moved to Stanley, where the last case occurred. The disease prevailed among the civil population also, but "the number of cases reported were comparatively few." The habits of the soldiers seem, as in Ceylon, to be very unsatisfactory, 26

Digitized by Google

cases of alcoholic poisoning and 6 of delirium tremens having been admitted, being in the ratio of 14·6 per 1000 of the strength. There appears to be a want of sufficient barrack accommodation both at Hong-Kong and in the Straits Settlements, and the drainage of the rifle range at Tanglin is still reported to be quite inadequate, and to this is attributed much of the prevalence of ague among the troops.

THE AMERICAN EXHIBITION.

DURING the splendid weather we have enjoyed this year vast crowds of people have thronged to the American Exhibition. The pleasure that has rewarded the effort of a visit may, in some instances at least, have also conveyed a few useful suggestions. The Exhibition, it is true, is small, and does not contain many remarkable exhibits. The enterprise has certainly not received the support it merited at the hands of American manufacturers. There seemed, at first, to have existed some lack of confidence, which must now be the subject of very keen regret on the part of those who failed to respond. "Buffalo Bill," however, has proved a host in himself, and we cannot regard his entertainment as altogether devoid of any bearing on questions relating to health. On the contrary, the vigour and physical agility of the entire troop must stimulate the love of wholesome out-door exercises. Such exhibitions are, therefore, likely to help those who by every means seek to improve the strength and endurance of the people.

Within the building of the Exhibition itself one of the most striking features is the plentiful supply of temperance drinks. Evidently this is a great problem. How can we provide a drink that shall be really palatable and yet free from alcohol; that shall consist in the main of water, and yet shall not contain the germs of disease too often present in what is called potable water? Messrs. John Matthews of New York seem in all but one important particular to have solved this problem. They have a magnificent marble fountain, standing some thirty feet high, where iced carbonated beverages are served from an apparatus carefully made so as to be free from all base metals that might affect the water. This water, further, is distilled in a special engine-house just outside the main building, and then aerated with compressed carbonic acid gas. Thus the water is perfectly safe, the pure syrups added give it a very pleasant flavour, and the only fault to find is the high price. While fourpence is charged per glass this cannot become a popular temperance beverage. Should some temperance stimulant be required, these waters can be mixed with the acid phosphate liquid prepared by Professor E. N. Horsford, which has a great sale in America. This consists of a solution of phosphates of lime, magnesia, potash, and iron, with phosphoric acid.

Close to the soda-water fountain will be found the interesting exhibits of Messrs. Wm. R. Warner and Co., American chemists. They exhibit a preparation called "bromo-soda," each dose of which consists of twenty grains of bromide of potassium and one grain of caffeine, made up in effervescing granules. The same firm show a great variety of soluble coated pills and granules, that are elegantly prepared and conveniently packed into very small compass. Their "ingluvin" powder is at least a historical curiosity. From time immemorial the Chinese and the Caucasians have mixed the gizzards of fowls with a variety of dishes, and this has been considered as a wonderful remedy for indigestion. In China chicken gizzards are placed in hot water, reduced to pulp, and mixed with spices, a spoonful being given at mealtimes. Experiments have now shown that the gizzard contains a powerful nitrogenous radical that possesses the qualities of pepsine, and is easily retained on the stomach.

Among other exhibits we noticed an automatic dispensary. By dropping a penny into an aperture, a pill corresponding to the inscription can be withdrawn from the apparatus. Such a happy-go-lucky method of treating human ailments is likely to lend itself to some abuses and not a few accidents; and we must confess that, even in this age of steam and machinery, we are not yet quite prepared to give a licence or diploma to a cast-iron mechanical medicine man. Messrs. Seabury and Johnson show plasters for which they have acquired a wide reputation throughout the United States. Messrs. Frank Giles and Sons exhibit a patent felt paper which is very well adapted to packing medicine bottles so as to prevent their breaking, and only costs sixpence the square yard.

An American Exhibition naturally contains alimentary products, and these, as tending to reduce the price of food, are of assistance in maintaining the health of the poorer classes. Among this class of exhibits will be found the Fairbank Canning Company and the Armour Canning Company of Chicago. Close by, the Johnston Fluid Beef Company distributes beef-tea to all the visitors, and thus seeks to increase the popularity of its useful and nutritious extract. Perhaps among the food exhibits the most remarkable are those of Messrs. Gordon and Dilworth of New York. Apart from a most luxurious display of preserved fruits, we have some calf's-foot-jelly mixed with port or sherry. The glass jars are closed in a patent manner, and the opening is large enough to allow the jelly to be taken out with a spoon, so that it need not be melted as when in bottles. All the preserves are in glass, and this helps to keep the flavour; nor can any chemical action occur, as is sometimes the case with tinned fruits, &c. Finally, we should not omit to mention that in the grounds there is a medical station with a physician in attendance, and that the Exhibition also possesses several ambulances. Thus it will be seen that there are at least a few points of special interest to medical visitors, though these are not numerous.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria at Pwllheli, by Dr. PARSONS.—This is a small town on the coast of Carnarvonshire, closely and irregularly built, the undue crowding together of houses being partly due to natural configuration. There are sewers in the place, but many of the houses are not connected with them, and both sewage and other filth, such as slaughter-house refuse, fouls the harbour. Midden privies prevail, and cause the customary nuisance. There is a public water service, but some pumps remain which deliver suspicious contents. Diphtheria first showed itself in May, 1886, and between that date and the end of March, 1887, 30 cases occurred in 18 households, with 10 deaths. Nothing was ascertained as regards the origin and spread of the disease beyond the usual story of personal intercommunication, and the report terminates with ordinary recommendations of an administrative sort.

Diphtheria at Haslemere, by Dr. AIRY.—This well-known Surrey district is in the Hambledon Union, but diphtheria has extended beyond its bounds. Thus, in the Witley sub-district of that union 6 diphtheria deaths took place in 1885, 12 in 1886, and 1 in the first quarter of this year; in the Farnham sub-district of the Farnham Union the deaths for the corresponding periods were 10, 7, and 2 respectively; in the Petersfield sub-district of the Petersfield Union they were 17, 18, and none respectively; and in the Fernhurst sub-district of the Midhurst Union they were 5, 5, and 1 respectively. Thus, it came to pass that the outbreak was being dealt with by four different medical officers of health, amongst whom there was no concerted action. In and immediately about Haslemere some 70 cases and 18 deaths were known of, and one main factor in its dissemination was school intercourse, supplemented by the intercourse between the neighbouring houses of the sick. Incidents bearing on this view are recorded, and an account is given of faulty sanitary conditions prevailing in the district. But Dr. Airy is careful to add that, so far as he was able to ascertain, the outbreak did not show any marked dependence upon the insanitary conditions that came under notice.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington. — Dr. Dudfield's report, as usual, takes cognisance of a number of matters which interest his district, in so far as it forms part of the metropolis as a whole. A staunch supporter of the action taken by the Metropolitan

Digitized by Google

Asylums Board, he regards the course adopted last year in perfecting the system of removing the sick direct from their homes to the hospital ships as having in large measure led to the diminution in the small-pox mortality; and he claims that the system in question was instituted upon his recommendation to the Asylums Board and to the Local Government Board. He also quotes the Registrar-General's statement to the effect that, whatever the cause of the failure of London to improve in its relation to small-pox to the same extent as the provinces, that cause came into operation long before the hospitals were opened. We doubt this, and we note that this conclusion is largely affected by the use which has been made of the mortality returns for the 1871 epidemic. Place these returns on one or other side of that dividing line and conclusions almost diametrically opposed to each other can be obtained. With regard to the present stage of the question of the spread of scarlatina Dr. Dudfield's criticisms of the report made by Professor Axe, and issued on the authority of Professor Brown, are worth reading. Other matters of general importance are dealt with in Dr. Dudfield's report, which forms a good *précis* of the progress made in matters relating to the general health of the metropolis. Reverting to Kensington itself, we find that with an estimated population of 173,500 the death-rate for 1886 was 15·9 per 1000, as opposed to 19·9 in the metropolis as a whole; and that the zymotic rate was 1·6, as opposed to 2·7 in the metropolis. A record is given of the action taken as to various matters affecting public health in the district; and as regards the pressing difficulty in dealing with the refuse collected in metropolitan districts, it is stated that a committee is considering the practicability of conveying it to the country for agricultural purposes. We shall be interested to learn the results of these deliberations in view of the public opposition to destructors.

Basford Rural District.—On a population of 49,148 there was during 1886 a death-rate of 18·7 in this district, this rate exhibiting an increase on that for 1885. The so-called zymotic diseases caused 108 deaths, of which 42 were from diarrhœa, 30 from whooping-cough, 17 from measles, and 10 from enteric fever. Each group of diseases is dealt with in the report, and its history is the more trustworthy because Dr. Boobbyer succeeds in getting a fair account of sickness returns by means of a voluntary notification. The prevalence of enteric fever shows some 25 per cent. reduction on the average of such occurrences during the previous ten years, and it is evident from the detailed record given that speedy and valuable action is taken to detect fresh attacks, and to deal with their causes. Amongst other work that has been carried out is the preparation of a code of bye-laws now ready for the consideration of the authority. Really good bye-laws are likely in course of time to have a most important influence on the future health of the people, and authorities would do well to give a sufficient amount of their time to a subject which at first sight appears dry and uninteresting. A new form of midden-privy is shown in a diagram. It exhibits such a vast improvement on the old-fashioned form in vogue in this district that its adoption could only effect improvement. But we do not like the capacity given to the structure, for it will favour too large an accumulation of excreta and refuse in localities which are getting populous, and the slanting slab intended to carry the excreta amongst the ashes fails, especially after recent cleansing of the receptacle, to ensure that complete mingling of contents which it is so important to obtain.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5784 births and 3333 deaths were registered during the week ending September 10th. The annual rate of mortality in these towns, which had steadily declined in the preceding four weeks from 23·7 to 18·9 per 1000, further fell last week to 18·8. During the first ten weeks of the current quarter the death-rate in these towns averaged 21·4 per 1000, and was 0·2 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·2 in Derby, 14·0 in Bristol, 14·1 in Norwich, and 15·6 in Huddersfield. The rates in the other towns ranged upwards to 25·2 in Manchester, 26·2 in Newcastle-upon-Tyne, 26·7 in Birkenhead, and 29·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding six weeks from 1301 to 792, further fell last week to 768; they included 469 from diarrhœa, 95 from scarlet fever, 83 from whooping-cough, 57 from "fever" (principally enteric), 32 from measles, 28 from diphtheria, and only 4 from small-pox. These zymotic diseases caused the lowest death-rates last week in Huddersfield and Halifax, and the highest rates in Birkenhead, Sunderland, Wolverhampton, and Bolton. The greatest mortality from diarrhœa was recorded in Cardiff, Hull, Preston, Wolverhampton, and Bolton; from scarlet fever in Liverpool, London, Sheffield, Manchester, Birkenhead, Oldham, and Bristol; and from "fever" in Sunderland, Leicester, and Birkenhead Of the 28 deaths from diphtheria in the twenty-eight towns, 18 occurred in London, 3 in Birmingham, and 2 in Liverpool. Small-pox caused 3 deaths in Sheffield and 1 in Bristol, but not one in Greater London or in any of the twenty-five other large towns. Only 4 cases of small-pox were under treatment on Saturday last in the Metropolitan Asylum Board hospitals receiving cases of this disease, of which one was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 178, 160, and 169 in the preceding three weeks, declined again last week to 160, and were 4 below the corrected average. The causes of 84, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Plymouth, Wolverhampton, Derby, and Cardiff. The largest proportions of uncertified deaths were recorded in Brighton, Sunderland, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·7 and 18·5 per 1000 in the preceding two weeks, rose again to 19·4 in the week ending September 10th; this rate was 0·6 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·2 in Paisley and 17·3 in Aberdeen and in Leith, to 21·1 in Dundee and 26·0 in Greenock. The 484 deaths in the eight towns last week showed an increase of 21 upon the number in the previous week, and included 45 which were referred to diarrhœa, 40 to whooping-cough, 11 to "fever" (typhus, enteric, or simple), 11 to scarlet fever, 5 to diphtheria, and not one either to small-pox or measles; in all, 112 deaths resulted from these principal zymotic diseases, against 111 and 102 in the preceding two weeks. These 112 deaths were equal to an annual rate of 4·5 per 1000, which exceeded by 0·2 the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 53 and 39 in the previous two weeks, rose again last week to 45, of which 11 occurred in Glasgow, 11 in Edinburgh, 8 in Dundee, and 7 in Aberdeen. The 40 deaths from whooping-cough showed a further increase upon recent weekly numbers, and included 9 in Edinburgh, 9 in Greenock, 8 in Glasgow, and 7 in Dundee. The 11 deaths referred to "fever" were within one of the number in the previous week; 3 were returned in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 11 fatal cases of scarlet fever also showed a decline; they included 5 in Dundee, 3 in Glasgow, and 2 in Perth. Of the 5 deaths referred to diarrhœa, 2 occurred in Glasgow and 2 in Greenock. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 73 and 71 in the preceding two weeks, declined last week to 66, and were 6 below the number returned in the corresponding week of last year. The causes of 60, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·3 and 37·5 per 1000 in the preceding two weeks, declined again to 27·9 in the week ending September 10th. During the first ten weeks of the current quarter the death-rate in the city averaged 30·1 per 1000, the mean rate during the same period being but 20·9 in London and 18·6 in Edinburgh. The 189 deaths in Dublin last week showed a decline of 65 from the number returned in the preceding week; they included 36 which were referred to diarrhœa, 17 to measles, 7 to "fever" (typhus, enteric, or simple),

Digitized by Google

4 to scarlet fever, 3 to whooping-cough, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 78, 48, and 65 in the preceding three weeks, further rose again last week to 77; they were equal to an annual rate of 11·4 per 1000, the rate from the same diseases being but 3·3 in London and 4·8 in Edinburgh. The fatal cases of diarrhœa, which had been 39, 30, and 31 in the previous three weeks, rose again last week to 36. The deaths from measles, however, showed a decline of 6 from the number in the previous week. The 7 deaths from "fever" showed a further increase upon the numbers in recent weeks, while those from whooping-cough were less numerous. The deaths both of infants and of elderly persons showed a marked decline from the high numbers returned in the previous week. Six inquest cases and 2 deaths from violence were registered; and 53, or considerably more than one-fourth, of the deaths occurred in public institutions. The causes of 28, or nearly 15 per cent., of the deaths registered during the week were uncertified.

THE SERVICES.

Deputy Surgeon-General R. W. Clifton has been appointed Principal Medical Officer to the Curragh Brigade.

ARMY MEDICAL STAFF.—Surgeon Richard Charles Kirby Laffan has been seconded for service under the Egyptian Government.

MILITIA MEDICAL DEPARTMENT.—Surgeon-Major J. R. A. Douglas, 5th Battalion, the Royal Fusiliers (City of London Regiment), resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

ARTILLERY VOLUNTEERS.—1st Glamorgan: Philip Rhys Griffiths, M.B., to be Acting Surgeon (dated Sept. 10th, 1887).

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Worcestershire Regiment: William Leonard Braddon, M.B., to be Acting Surgeon (dated Sept. 10th, 1887).—1st Volunteer Battalion, the Northumberland Fusiliers: Acting Surgeon C. Farmer resigns his appointment (dated Sept. 10th, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon James Robertson has been placed on the retired list of his rank (dated Sept. 2nd, 1887).

The following appointments have been made:—Surgeon Alfred E. Weightman, to the *Garnet* (dated Sept. 10th, 1887); Surgeon George T. Collingwood, to Chatham Hospital (dated Sept. 10th, 1887); and Surgeon James Crevie, to be Surgeon and Agent at Belhelvie (dated Aug. 31st, 1887).

"Audi alteram partem."

THE TREATMENT OF PERFORATING ULCER.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the cases of perforating ulcer recorded by Mr. Bland Sutton and Mr. Pryce in THE LANCET of July 2nd, for I have continually to treat a number of cases of this troublesome complication in the Leper Asylum here. I must, however, comment on a point in treatment, which I am aware is not new, but which does not seem to be sufficiently recognised. I have before me notes of three cases in which I cut down upon and stretched the sciatic nerve for painful perforating ulcer. In the first case the ulcer healed and the pain vanished. In two months, however, it returned so severely that the patient begged for amputation. I then stretched the external popliteal and slit up a sinus in the sole, making a large T incision. Since that date (five months ago) he has made no complaint. The ulcer is not quite healed and seems inclined to remain stationary. In the second case the pain was relieved, the swelling of the foot diminished, and the ulcer lessened in size. In five months more the foot became very swollen and inflamed, the ulcer very painful, and dead bone was removed. He also begged for amputation. Instead of this, the foot was freely incised in various directions, and sloughs carefully removed as they formed. In a month the ulcer on the sole was nearly healed, the incisions were granulating well, and there was no pain except when he tried to walk on the foot. In the third case there was temporary relief; but the foot became gangrenous, and at the patient's own request the leg was amputated a month later. The posterior tibial nerve was greatly thickened, the fibres being separated by gelatinous-looking material. The stump was perfectly healed in two months more, and the patient was getting about with a wooden leg.

I could multiply examples, but these are enough for the present purpose. My experiences of nerve stretching are still accumulating, and are not yet ripe for publication; but this I feel justified in saying, as a result of observation so far, that amputation for perforating ulcer should never be thought of till nerve stretching and free incision of the ulcer have been thoroughly tried.

I am, Sirs, yours truly,

BHAVEN RAKE, M.D. Lond.,
Medical Superintendent of the Trinidad Leper Asylum.

August 13th, 1887.

PAIN AND ITS INTERPRETATION.

To the Editors of THE LANCET.

SIRS,—I have read with great interest the articles published in THE LANCET under the above heading. They have already called forth letters of protest, at which I am not surprised, containing as they do much that is debatable.

As a general proposition, it may safely be said that pain is of service to mankind. To this, I imagine, no one will demur. It is one of the solid foundations on which our treatment is based. Proofs of it are abundant. Take, for instance, an injured joint. A man gives his knee a violent wrench; the structures are severely strained; some of the ligaments are ruptured; and synovitis follows. The man has pain, which is increased on movement, and so instinctively the joint is kept fixed and is given rest. The surgeon fixes the knee on a splint, absolute rest is maintained, but still pain continues. At first the pain was useful, and amongst other things pointed out the treatment; but when rest is obtained, of what use is the pain?

In many and various other instances the utility of pain is clear; but to say, as was said by Mr. Gillies, that "pain comes at the right time," and "never comes where it can serve no good purpose," is palpably fallacious. Take the case of a woman with that truly terrible affliction, scirrhus of the mamma. It begins as an excessive epithelial growth, at first perhaps of only a very few cells. A small tumour is developed, and for weeks or months she may be completely unconscious of it. Now pain in her case, to be of good purpose, should be felt quite early in the course of the important change. What do we find? For months, may be, she is quite ignorant of the fact that she has within her the beginning of what will ultimately be her end. The tumour grows, neighbouring structures become contaminated, and pain comes on and persists, which by the exhaustion it induces hastens on the inevitable. In this stage, of what service is her pain? The diagnosis is made, the disease is too far advanced for operation, the patient knows that she is beyond the reach of surgery, and so, tortured with pain night and day, she waits, and prays for a speedy release. And yet the writer stoically says, "Pain is merciful."

Further on he says: "Pain is in direct proportion to the powers of repair—that is, to the probability of recovery." So it appears that the woman who is the most affected with cancer and suffers the most pain is more likely to recover when operated on than the one who has the small, initial, and painless cancerous tumour! Is this the teaching of modern surgery? Is this the practice of its disciples—the writer of the articles amongst them? The one fact that stands out clearly in the statistics of the operations for cancer is that the sooner the patient is rid of the tumour the better will be the prospect; and could we but diagnose the affection in its painless state, when it first becomes heterologous, and acted accordingly, the prognosis would be extremely favourable. This, unfortunately, we are unable to do.

The writer would have us believe "that the measure of pain which attends an injury or a disease is a prophecy in that same measure of recovery." If so, then the more acute and painful a pleuro-pneumonia, the more pain after a fractured rib the more pain after a ruptured bladder, the

Digitized by Google

more acutely strangulated and powerful a hernia, the more excruciating the headache in meningitis, the greater are the prospects of recovery! Different temperaments do not enter into his calculations; it is one absolute rule—"the more pain, the more likely to recover." If he follows his own conclusion he will most assuredly be led into many a pitfall.

If pain be the unmixed blessing we are asked to believe it is, why do we in all cases endeavour to palliate it? Why does health suffer from its persistency? Why often when pain ceases does health improve? And why do we completely abolish it during the performance of operations? Pain is a universal human legacy. It is the penalty we pay for our high state of development. It is what generations of medical men in all climes have striven with all their strength and knowledge to lessen or to annul. We walk in their footsteps, but with more powerful weapons against the dread inheritance. Others will follow us, and so the warfare will ever continue.

I am, Sirs, yours faithfully,

E. R. WILLIAMS, M.R.C.S.

Richmond Gardens, Forest Gate, E., Sept. 12th, 1887.

To the Editors of THE LANCET.

SIRS,—Relative to your annotation "What is Pain?" and also to the articles on the "Interpretation of Disease," may one inquire if it is not as absurd to speak of the "purpose of pain" as it would be to talk about the *purpose* of hæmorrhage from a severed vessel? In the latter case the function—it may be called—of conveyance is interfered with and blood flows out and is lost, but no one talks about the *purpose* of loss of blood. It is perceptible to our senses just as much as pain is, and is additionally perceptible to sight, and no doubt serves as a warning to us to take measures to check it; but would anyone therefore speak of the *purpose of hæmorrhage* as "protective"? Yet you write—"the purpose of pain is doubtless protective." Hæmorrhage in general terms is a consequence—a sign—of failure, in greater or less degree, of a function of vascular tissue—viz., *conveyance*. So pain is a consequence, a sign of failure of function of nerve or other tissue; and, as a failure, as a defective performance, it has no more *purpose* than hæmorrhage or any other failure or deficiency has. "Purpose" is surely confined to normality, and when the natural conditions under which an organ or a tissue does its work are changed to the extent of causing, for example, hæmorrhage, or pain, or what not, is it not beside the question to talk of "purpose" in it all? All "purpose" was probably expended in providing for the normal working of parts. What "purpose" there may be in disease or its symptoms—e.g., pain, hæmorrhage, &c.—is due to the persistence to the survival of some elements of normality in function, and it is a mistake to speak of the "purpose" of what is really the *failure of purpose* and nothing more.

I am, Sirs, your obediently,

Sept. 1887. G. C. LIPPINCOTT, M.D., U.S. Navy.

To the Editors of THE LANCET.

SIRS,—It is in no contentious spirit I write you again on this most important question, but in the hope, as I have already expressed, that some good will come of it. Dr. Collins compels me to quote a sentance from my last paper: "*Now, let me say that there are serious exceptions—apparent exceptions—to this law of pain.*" I leave him to judge whether I meant to cover cancer by that. I made the expression general for a purpose, and that purpose has been served so far well. I hoped to get men of greater knowledge and experience than I can justly claim to give the fulness of detail that I so clearly saw was at this very point necessary. Towards that Dr. Collins in his two letters has contributed nothing. When I said I did not understand his explanation, I did so honestly fearing that there might be something more in his theory than I could then see—something that his words failed to convey with sufficient clearness. But now that Dr. Campbell has put the matter in a very simple effective expression I am quite ready to accept it, and that entirely in favour of my view of pain, not against it. But let me indicate that the method or process of the evolution of pain is a question at every point quite distinct from the purpose of pain. It is with the meaning, the motive of pain, that I am concerned, not with the process of its evolution. Mr. St. Clair Buxton looks at the matter from the same point of view as Dr. Collins; but that "pain stands out simply as an evidence of evolution" is what I cannot accept. Pain has some other and higher purpose than that.

I am not clear as to what Dr. Collins means in his reference to anæsthetics. The use of anæsthetics in surgical operations is clearly outside the question at issue. Their administration to suppress natural pain is not rarely a questionable proceeding; it is at best a temporary expedient. I think it was Lord Macaulay who said that the suppression of pain by opiates was like taking the warning rattle off the snake but leaving it in full possession of its fangs. I need not elucidate this truth to your readers; they are daily familiar with the fact. In the measure that we know the cause of pain and understand its meaning, I believe anæsthetics shall have more limited use.

There are several points in Dr. Campbell's excellent, thoughtful letter that I prefer not to deal with at present. If I am not mistaken, Dr. Campbell could put us much in his debt by answering his own questions. Would it be too much to ask him at convenience to do so?

I am, Sirs, your obedient servant,

Brockley, S.E. H. CAMERON GILLIES.

DEATH FROM CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—As it is important that a permanent record should be kept of all cases of death arising out of the administration of anæsthetics, I send you particulars of a death which recently occurred at the Chester General Infirmary—a short account of which has appeared in some of the daily papers.

On Aug. 16th last, a patient, W. L——, aged thirty, was admitted to the infirmary suffering from necrosis of a metacarpal bone, the result of an injury received five months previously. It being considered necessary that the piece of dead bone should be removed, Mr. Lees, house surgeon, on Aug. 18th, asked me to give chloroform for him whilst he performed the operation. The patient had no symptoms of cardiac disease, and both Mr. Lees and myself examined the pulse immediately before the operation, and found it regular and healthy. I administered the anæsthetic on lint, the patient coming very rapidly under its influence (less than three minutes being occupied in obtaining this result), and not more than two drachms of chloroform being used altogether. Mr. Lees commenced the operation, and in a few seconds it was noticed that the pulse became very feeble and flickering and the respiration shallow. Almost immediately after this both pulse and respiration stopped. Artificial respiration by Silvester's method was at once set up, hypodermic injections of ether given, nitrite of amyl sprinkled on lint placed over the nostrils, mustard applied to the heart, and an enema of brandy-and-water administered. Attempts to restore the patient were kept up for more than an hour, when the case was abandoned as hopeless. At the first symptoms of syncope, Dr. Stolterforth, one of the honorary physicians, was sent for, and was present while the efforts at resuscitation were being carried out.

A post-mortem examination was made on the following day by Mr. Lees. The right auricle was found very much distended with blood; all the valves of the heart were healthy, but its muscular substance was brown, and the walls thin and fatty (at the apex of the left ventricle the muscle was not more than one-eighth of an inch in thickness). Under the microscope many of the muscular fibres showed a central deposit of oily material. There were also some pleuritic adhesions.

At an adjourned inquest held on Aug. 26th, the coroner, after hearing the evidence, said "the jury could have little doubt that the deceased came by his death accidentally while under chloroform properly administered for the purposes of an operation. The state of the man's heart was not discoverable at the time of the operation, so not the slightest blame attached to the doctors." The jury expressed concurrence with the coroner and returned a verdict to that effect.

I am, Sirs, your obedient servant,

ALFRED MANN, M.B., C.M.,

Sept. 8th, 1887. Visiting Surgeon, Chester Infirmary.

"UNUSUAL FORM OF SCIRRHUS OF THE BREAST."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 10th, a case is mentioned on p. 520 of an unusual form of scirrhus of the breast, in which Mr. Treves states that he has not seen an example in which a nodular disposition of the growth has been evident. I venture to think this form is by no means so rare as Mr. Treves imagines. I have seen three such, and in all the progress towards death was exceedingly rapid. In none of these cases were both breasts involved, but the skin over the second breast was in one case especially very markedly nodular, the nodules varying from the size of a small shot upwards. I am, Sirs, yours obediently,

Harley-street, W., Sept. 14th. W. BRUCE CLARKE.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NORTHERN ATTRACTIONS.

THE Newcastle Exhibition may now be said to be at its very best. Up to this, nearly one million and a half of visitors have passed in. The shortness of daylight is amply compensated by the brilliant electric lighting of the grounds. A course of scientific lectures has been commenced in the theatre of the building, and the following is included—"The Beginning of Life: the Germ Theory of Disease," by A. C. Monro, M.B., D.Sc., medical officer of health for South Shields and Jarrow. Any of your readers who can come to Newcastle for a day or so will be well rewarded for their journey, for, as well as the usual objects of interest to be found in all industrial and fine art exhibitions, the Newcastle display has specialities of its own, such as the Armstrong ordnance in all weights and stages, the machinery in connexion with mining, engineering, and hydraulic works, while the ship models of vessels for peace and war are admitted by competent judges to be, so far, unsurpassed. The show, too, of surgical instruments exhibited by Messrs. Brady and Martin, McQueen, and others of this city, is most complete, and indeed would be difficult to match. I shall, however, say little about these exhibits, as they should be seen by every medical visitor to the Exhibition. There is another attraction offered to visitors now by the opening a few days ago of a new line of railroad from Alnwick to Cornhill, a most interesting and historical part of the borders; and Northumberland is now accessible to the tourist. As this new line is not yet traced on the maps, and has not, I believe, found its way into any of the railway guides, a short sketch of the route may perhaps prove useful. The line in all is about thirty-six miles, running from Alnwick to Cornhill, a village about two miles from Coldstream on the Tweed, passing quite near Flodden Field, winding at Wooler round Cheviot, and passing Tankerville Castle. It has seven or eight stations, convenient to some of the best trouting streams in England; and, while writing of trout, I would advise all anglers to come at once, as the northern rivers are just now in perfection, and may be reached with great facility by this new line through Central Northumberland.

Newcastle-on-Tyne, September 13th.

DUBLIN.

(From our own Correspondent.)

REFORMATORY AND INDUSTRIAL SCHOOLS OF IRELAND.

FROM the twenty-fifth report of these institutions it appears that the admissions to reformatory schools in 1886 were 203, showing an increase of twenty-nine as compared with the previous year. Of the five deaths which occurred, three were from lung diseases, one from mesenteric disease, and one not classified. Of the 7099 children in industrial schools during the past year, seventy-nine deaths took place, of which forty-five were due to diseases of the lungs, six to fever, and two to scarlatina. The educational status of the inmates of industrial schools plainly evinces the deplorably illiterate condition of the class of children who are admitted year by year. No less than 61 per cent. of the children who were admitted in 1886 were quite illiterate; and the returns of previous years are likewise evidence that the normal educational status of children sent to these institutions yearly deteriorates. The inspector draws the attention of managers of reformatory and industrial schools to the importance of having a careful examination made of the arms of all children admitted to their schools to ascertain if they have been vaccinated in infancy, as it appears that a large proportion of the children present no traces of primary vaccination, and are unprotected against the danger of contracting small-pox. With regard to other infectious diseases which children are so liable to contract, the managers are advised to make arrangements for setting apart a small day-room and dormitory for the reception of recent admissions and their retention in these "observation wards" for a period of two weeks after admission. Many children are committed to industrial schools from the crowded tenement dwellings in large towns. Some of these may have recently suffered from infectious or contagious diseases, or may have been in contact with affected persons to such an extent as to become carriers of infection. The necessity for some arrangement of the kind recommended has been recently shown by a case in which a child admitted to a country industrial school communicated typhus fever to two Sisters of Mercy, both of whom died from the disease thus accidentally introduced.

A CENTENARIAN.

A man named Crooke died in Tipperary Workhouse last week at the advanced age of one hundred and six years. Until a month before his death the man is said never to have been sick a single day. He never wore a collar or cravat, but, in his own words, "gave his breast to the breeze, so that his lungs always had room to blow."

CORPORATION OF CORK PRESENTMENTS.

At a meeting of the Town Council held last week, the following presentments were passed—viz., Cork Fever Hospital, £500; North Infirmary, £350; South Infirmary, £350. The presentment for the District Lunatic Asylum, amounting to £2812 19*s.* 7*d.*, on a division was postponed, as a protest on account of the authorities not appointing as governors the members of the corporation selected for the office. As passing this presentment is mandatory on the corporation, the protest appears a rather insignificant method of retaliation.

Samuel Stuart, M.D., J.P., died at his residence at Donaghadee last week, aged seventy-three years.

Dublin, Sept. 13th.

BELFAST.

(From our own Correspondent.)

QUEEN'S COLLEGE.

FROM the report of the President (Dr. Porter) of the Queen's College, Belfast, for the session 1886–87, I learn that 110 students entered the College for the first time during the session, and the total number of students enrolled in each department during the session was as follows:—Arts, 170; medicine, 240; law, 22; engineering, 12; and as 21 of these attended in more than one faculty, the aggregate total of individuals enrolled was 423. In the Faculty of Arts 9 ladies attended, but owing to the College Charter they are not eligible for any awards. The President reports that not a single case of breach of discipline has come before the Council, and the reports of the deans of residence, which are appended, are most favourable. The success of Belfast students at the Royal University has been very great. At the annual meeting of the Royal University held last October, the Vice-Chancellor (Lord Emly) said: "This year at our first university, second university, and B.A. degree examinations, the total number of exhibitions awarded was sixty-five, and of these the students of Queen's College, Belfast, carried off no fewer than twenty-two, and they also won a large proportion of first-class honours." In competing for honours in the Royal University, the Belfast students are at a great disadvantage as

Digitized by Google

compared with those educated in or near Dublin. All the honour examinations are conducted in Dublin, some of them after the close of the pass examinations, and this involves a larger expenditure of time and money than most young men from the north can afford; and hence students of great promise not unfrequently content themselves with a mere pass. The President reiterates what he said in his last report, that the time must surely soon come when it will be no longer necessary for so large a body of students as the Belfast Queen's College furnishes yearly to the University to go to Dublin for their examinations and degrees. They receive their education in Belfast under professors of acknowledged eminence, and, with the assistance of a staff of well-selected extern examiners, the President maintains that in the Queen's College they could conduct all the examinations with equal fairness, and with at least equal thoroughness. Belfast has now a population of 230,000. It is the commercial capital of Ireland and the capital of Ulster, which has a population of 1,700,000, being more than one-third of the entire population of Ireland and nearly one-half of that of Scotland. In Dublin there are two universities side by side, while in Scotland there are four. The President asks, Why should Belfast not be made the seat of a university for Ulster? The present arrangements for conducting university examinations and granting degrees are not satisfactory; they are not fair, Dr. Porter says, to the people of Belfast and the province of Ulster. The Royal University does not, and from its constitution cannot, supply the educational requirements of the people of the north of Ireland. There is, the President remarks, in Belfast an admirable nucleus for a university. There are 1500 students, *alumni* of the College; there is a large body of students, an efficient professorial staff, an excellent library and museums; and with a small expenditure of money the laboratories might be made fit for thorough practical training. What the College wants is independence, and freedom from an external control which is not helpful. The President points to the great success of Scotland as a nation as being due, in no small degree, to its universities; and in many respects Ulster resembles Scotland, and he asks Her Majesty, in this year of Jubilee, to grant to Queen's College, Belfast, a university charter, that it may be able more efficiently to promote the great object for which it was founded, "the better advancement of learning among all classes of Her Majesty's subjects in Ireland." There is no doubt that the Irish education question is far from being settled. The people of the north have not taken kindly to the Royal University, which is a mere examining board; and, as far as Ulster is concerned, the establishment of a university in Belfast would be most popular. The President refers to the success of the Belfast students at Oxford, Cambridge, the Middle Temple, London, as well as at the Royal University; and concludes his report with the address presented to the Queen on the occasion of her Jubilee by the President and professors of Queen's College.

Belfast, Sept. 13th.

Obituary.

JOHN SHEA, M.D.,

PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL, AND MEDICAL OFFICER OF HEALTH TO THE BOROUGH OF READING.

IT is with sincere regret that we have to announce the death of Dr. Shea, of Reading, at the early age of forty-nine, on Tuesday the 6th inst., from an attack of apoplexy. He had felt a little unwell while at breakfast, and retired to his study to be quiet. His family shortly afterwards heard him call, and on entering the room, found him fallen forward from his chair unconscious. Several of his medical neighbours and colleagues at the hospital were soon in attendance, but their efforts were unavailing, and he died in a few hours from cerebral hæmorrhage.

Dr. John Shea was the son of Dr. John Shea of Blackfriars-road, who was one of the oldest practitioners in London, and died only a year or two ago, an octogenarian. Thus Dr. Shea, jun., the subject of this notice, inherited a tendency to longevity. His early death is an instance of the interference with this natural disposition by birth and residence through childhood and early life in London, in a district known to be among the least healthy. At a period when the present educational activity was commencing, Dr. Shea was afforded the advantage of a sound classical and mathematical education, and in due course took his degree in Arts at the London University. He became a member of the Royal College of Surgeons in 1858 and M.D. St. And. in 1861, and settled in general practice in Kennington, where he continued till 1870. A severe illness obliged him to relinquish practice in town, and seek a restoration of health in the country. He retired to Reading for this purpose, where many of his wife's relatives are influential bankers and brewers. The passing of the Public Health Act in 1872 created the office of medical officer of health, to which Dr. Shea was elected, as well as to that of the rural and urban sanitary districts of Wokingham. In due course he became physician to the Royal Berkshire Hospital. In discharging the duties of these offices and that of a consulting physician Dr. Shea passed the remainder of his life. It is not too much to say that his pure, noble, and unselfish nature endeared him to everyone with whom he was brought in contact. Among his professional brethren he was a universal favourite, for he had the happy gift of amalgamating discordant natures, and making his professional brethren friends who might otherwise be estranged. As one of the vice-presidents of the Pathological Society of Reading, he did much to promote its interests, and was mainly instrumental in bringing about the establishment of the new medical library and pathological museum in association with the hospital, which is the centre for professional reunion for the whole neighbourhood. The large numbers attending his funeral, though of a private nature and simple in form, bore testimony to the affection with which one was regarded whose animating principle through life was "to do justly, to love mercy, and to walk humbly with his God."

JAMES BARR MITCHELL, M.D., L.F.P.S.

DR. MITCHELL, who died somewhat suddenly on the 26th ult., was the son of Mr. Alexander Mitchell of the Apothecaries' Hall, Glasgow and was born in 1818. Educated at the High School and the University of Glasgow, he took his degrees in 1838, and completed his medical studies at Paris and at Padua. He made a special study of botany, a science he pursued under the friendly guidance of the late Sir W. Hooker, with whose family his own were on terms of intimacy. Between 1841 and 1846, Dr. Mitchell accompanied the late Earl Somers as private physician on several prolonged explorations in Syria, Egypt, Greece, and the remoter parts of Asia Minor; Sir H. A. Layard for a time forming one of the party, as did also Mr. J. Harrison Allan, whose beautiful "Pictorial Tour in the Mediterranean" illustrates some of the little known classical spots visited by the travellers. In 1845 he married the daughter of Mr. Archibald Robertson of Liverpool, a gentleman well known in the shipping world. For many years afterwards he resided partly in France and partly in England, devoting himself to various scientific pursuits. He introduced from France the process for manufacturing commercial albumen from the serum of blood, and was the first to make practical trial in England of the Arcachon system of oyster culture. In the introduction of Condy's fluid Dr. Mitchell took an active share, and his enthusiastic advocacy greatly promoted the popularising of that now well-known sanitary agent. In 1868 he was awarded the silver medal of the Naval Medical Congress at Havre for his paper on the Permanganates. Just before his death he was occupied with experiments to prove that salmon smolts could be advantageously reared in a limited salt-water area.

Dr. Mitchell was a member of the old Anthropological Society and of the Society of Biblical Archæology. He was a man of wide experience, deep reading, and much culture. The deceased gentleman leaves a wife and two sons to mourn a loss which will be sincerely shared by a wide circle of friends both at home and abroad.

DR. ERNST AUGUST MATTHIÄ.

THE "Romance of Medicine" has yet to find its author and scantiness of material will be the least of his difficulties. From "still life" to *la haute politique* there is enough to inspire a dozen novelists. Its characters are to be found where they are hardly to be suspected—even in retired little townships like Wülflingen, near Winterthur, in Switzerland,

Digitized by Google

where on the 15th ult. died one of the last survivors of the ill-starred rising known as the "Frankfurter Attentat" of 1833.

Ernst August Matthiä was born at Frankfurt-on-the-Main in 1812, son of Dr. Friedrich Christian Matthiä, rector of the Gymnasium in that city. He was barely of age, and still at the literary period of professional study, when the Federal Diet by its severely restrictive press laws aroused to madness the younger and more advanced of the citizens. The *Burschenschaft* took an active initiative in resisting the oppressive enactments, and young Matthiä, with a band of other students, reinforced by a considerable following of peasants, conceived the daring plan of blowing up the Diet. On April 3rd, 1833, the attempt came off. The conspirators stormed the guard-house, and were proceeding to effect their purpose when the military attacked them in force, arrested some of the ringleaders, and put the main body to flight. Matthiä was not taken till the following evening. With nine comrades he was subjected to a tedious State process, and finally condemned to imprisonment for life in the House of Correction.

Sentence was passed on June 18th, 1836, and made public on October 19th. Appeal was lodged against it with the Ober-Appellations-Gericht at Lübeck, and while it was under consideration six out of the ten prisoners, with the connivance of the turnkeys, and also, it is said, of the police on guard, succeeded in escaping. Matthiä and a medical student named Fries (who afterwards settled down in practice at Siffach, in the canton of Basle, where he died full of professional honours) fled to Frankfurt and remained in hiding for five weeks, continually changing their quarters, and assisted by their friends in the press, who published announcements of their safe arrival in more than one foreign port. At last both of them, skilfully clad, wearing spectacles, and with complexion painted, drove in a handsome turn-out to Hoch-heim, where they passed the night; on the evening of the following day they crossed in a boat to Mainz, journeyed through Rhenish Hesse and Rhenish Bavaria to France, and finally found an asylum in Switzerland.

At Zürich Matthiä, now able to breathe freely, applied himself with characteristic energy to the study of medicine, and graduated with distinction at that school in 1839, after which he settled in practice at Wülflingen, near Winterthur. As a practitioner he was highly respected, not only by the cantonal population of his adoption, but by the numerous foreign sojourners (English and American included) in that picturesque neighbourhood, with its interesting records of Roman occupation and its memorials of Zwingli, Gessner, Pestalozzi, and Sulzar. In 1848 he and the remnant of his comrades were amnestied, and since that year he often visited his native town, where he was ever cordially welcomed. Having lived down his "compromised" youth in steady professional work and philanthropic citizenship, he contributed to one of the editions of Brockhaus's "Conversations-Lexicon," a plain narrative of the "Attentat" in which he bore a part. Three only of his fellow-conspirators survive him, one of them a physician in Germany and father of a distinguished professor in that country.

DR. FRANZ SCHOTT.

A STIRRING and eventful career has just been closed by the death of this well-known army physician at Stuttgart on the 30th ult. Only his early youth and his declining years were spent in his native land. He was born at Steinheim-on-the-Main in the paternal parsonage in 1820. His father, who became successively dean of Geislichen and Herrenberg, sent his son to the gymnasium at Ulm, and thereafter to Stuttgart, where his preliminary education was completed. Between 1837-41 he studied medicine at Tubingen, and in 1842 passed with much credit the State examination and graduated as Doctor in the same year. He repaired to Wurzburg, where he held the post of assistant physician; but academic and civic practice seemed to him to offer an inadequate outlet for his energies. He entered the Dutch Army Medical Service, having previously qualified by an honourable examination at the University of Utrecht, and after a brief visit to his parents he set out for Java by the then tedious and not over-attractive sailing route round the Cape of Good Hope. His first destination was to Sumatra, where the Dutch were carrying on a desultory war in the southern part of the island with the indigenous tribes, among whose savage characteristics cannibalism was not the least pronounced. For six years he saw a good deal of active service there as surgeon to various military detachments, and in 1848, when the tide of revolution was sweeping Germany, he passed his second State examination in Batavia. His next scene of activity was the islands of Borneo and the Celebes, where he was several times under fire, and where, —an even more dangerous experience than that of bush fighting—he encountered and lived through the epidemics which told so terribly on the Dutch arms. Thanks to indomitable pluck, backed by a splendid constitution, which won him the name of the "iron doctor," he continued to earn the most honourable mention in the despatches, when at length a sharp liver attack reminded him of the limits of his health, and constrained him to return home. This was in 1859. Two years thereafter he resumed service in the Army Military Department of the Dutch Indies, this time as directing physician of the first class, corresponding to the post of "General-Arzt," in a German army corps. In 1864, after twenty years' service of a peculiarly active kind, he was induced to retire on a pension, and returned to his native parts, settling down in Stuttgart. He was very Dutch in his ideas and sympathies, and possessed the citizenship of that country, whose usages, particularly in education and public life, he was seldom tired of dilating on, admiringly, to his compatriots. He never forgot, however, that he was a German by birth, and took an enthusiastic interest in all the movements which finally culminated in the proclamation of the Kaiser William as head of the German Empire at Versailles. These events, and the national development that flowed from them, gave peculiar interest to the last two decades of his life, and kept him at an intellectual fever heat, which impelled him to an energy of occupation far beyond his years. He had made himself a proficient in the minutest details of Dutch history—a subject on which he wrote a number of learned and original papers. His last years he devoted to an autobiography, for which those of his friends who were allowed to see it predict a cordial reception from the reading public, abounding as it does in most interesting sketches of the flora and fauna of the Dutch Indies and the Bornese Archipelago, to say nothing of the thrilling incidents of the numerous expeditions in which he bore so honourable a part.

Medical News.

ENTERIC FEVER AT CHESHUNT.—Many cases of enteric fever have occurred recently at Cheshunt, Herts, and three deaths are reported to have taken place. The local board are exerting themselves to check the epidemic.

ANTHRAX. — An outbreak of anthrax is reported to have occurred amongst a herd of dairy cows at Limington, near Yeovil. The disease has also been prevalent on several farms in Lancashire.

FROM Brunswick a rather severe outbreak of trichinosis is announced. Some 130 persons are now labouring under the malady, and in each case it was found that fresh pork or fresh sausage had been consumed.

BURY AND SUFFOLK HOSPITAL.—On the 8th inst., the two lower wards of this hospital, which have been undergoing improvements, were re-opened by Lady Alwyne Compton and the High Sheriff, in the presence of a large and influential assembly of friends of the charity.

A CAUTIOUS PREACHER.—During the prevalence of scarlet fever in Plainwell, Michigan (says *Sunday Words*), all the churches are closed. The Baptist pastor sends his sermon weekly in a printed sheet to all the members of his flock.

ATTEMPT TO POISON A REGIMENT. — The Allahabad correspondent of the *Daily Chronicle* reports an attempt on the part of some miscreant to poison, by means of arsenic put into a beer cask, the men of the Borderer's Regiment stationed at Fettergarh. Forty of the men were made ill by partaking of the beer, but recovered.

A LAZARETTO FOR THE CANARIES. — The Spanish papers say that plans are being submitted to the Government for the erection of a lazaretto in the Canary Islands, the want of which is becoming yearly more and more urgent, as the traffic between the south-west of Europe and America, and also the west coast of Africa, is increasing.

TESTIMONIAL.—A few days ago Miss Ethel Manson, lately matron and superintendent of nursing at St. Bartholomew's Hospital, was presented by some of the members of the governing body and of the medical staff with a magnificent chest of table plate on the occasion of her resigning her post on account of her marriage with Dr. Bedford Fenwick.

OPHTHALMIA AT THE NORWOOD SCHOOLS. — The Lambeth Guardians have received a report of a satisfactory character with respect to the existence of ophthalmia at the Norwood School. The term for which Dr. Stevenson, the medical officer in charge of the ophthalmic cases, was appointed having expired, it was resolved to continue the appointment for another three months.

THE PECULIAR PEOPLE AGAIN.—Some dissatisfaction has been expressed by the inhabitants of Stanway, near Colchester, in consequence of the refusal by the coroner to hold an inquest on a girl, aged about sixteen, daughter of a member of the sect calling themselves the Peculiar People, who died without having the advantage of medical attendance. The reasons stated to have been given by the coroner for not holding an inquiry were that the girl was over sixteen years of age and did not desire the services of a medical man, and that she appeared to have received from her friends every attention in her illness. The "cause of death" was of course left blank in the certificate of burial.

THE Exhibition of Naval Architecture and Models, opened on Jubilee Day at Plymouth, the profit from which was intended to be devoted to augment the funds of the Royal Albert and the South Devon and East Cornwall Hospitals, seems to have proved, financially, a grievous failure. Instead of there being, as was expected, a goodly balance to hand over to the treasurers of the above-named charities, the promoters of the exhibition are some pounds out of pocket.

POLLUTION OF THE THAMES.—On Wednesday last, at Chertsey Petty Sessions, the Rural Sanitary Authority were summoned at the instance of the Thames Conservancy Board in respect of a pollution of the Thames by means of a drain discharging into the Bourne at a point about two miles from the junction of that river with the Thames. A full bench of magistrates convicted the defendant authority unanimously, the fine imposed being £50 and costs. This was the second conviction.

DONATIONS TO MEDICAL CHARITIES. — Miss E. J. Forster, part owner of South Hetton and Murton Collieries, has given £200 towards the cost of the Hartley wing of the Sunderland Infirmary. Mr. Stephenson Clark has given £50 towards the same object.—Mr. Henry Lewis, of Springfield House, Preston, has given £500 towards the endowment fund of the infirmary of the town.—The Earl of Stair has contributed £100 towards the fund for liquidating the debt on the Ayr County Hospital.

HOSPITAL SATURDAY FUND.—Sir E. H. Currie, speaking at a meeting at the London Hospital for the purpose of hearing the report of this year's efforts, said the total amount realised by the collections reached £12,000, a sum greatly in excess of that of any previous year. At Bolton the sum obtained in workshops and factories by a Saturday collection in aid of hospitals amounted to £1150. At Leamington the collection for a similar purpose reached £226 15s.

HEAT AND DROUGHT IN ODESSA.—The Odessa correspondent of the *Daily News* states that the heat there has been most distressing. There has been no rain. The hospitals, he says, are crowded and the death-rate has risen. There is a great dread of the importation of cholera by Mediterranean vessels, notwithstanding the quarantine regulations. The city sewers are neither disinfected nor flushed, and all the local conditions are unhappily only too favourable for the spread of a serious epidemic.

DEATH FROM BLOOD POISONING.—On the 3rd inst. Mr. Henry Wood, county coroner, held an inquest at Claxton on the body of a boy aged fifteen years, who died on the previous day. According to the evidence, deceased was suffering from a large boil on his arm, and he asked the foreman to cut off the top. He attempted to do this, it appears, with a rusty knife, and deceased also himself repeated the attempt several times. A verdict that deceased died from blood poisoning caused by opening the boil with a rusty knife was returned.

PAUPER LUNACY.—The charge on poor-rates for the care and maintenance of insane paupers has been steadily increasing of late years. The *Metropolitan* publishes the following statistics: In 1876 there were 55,515 lunatics chargeable to the poor-rates; by 1877 the number was 57,221; in 1878 it had increased to 58,942; in 1879 the number was 60,165; in 1880 it was 61,594; in 1881 it was 63,524; in 1882 there were 65,319 insane paupers; in 1884 there were 68,736; and in 1886 the number had risen to 70,820—an increase in the ten years of about 30 per cent.

SHEFFIELD GENERAL INFIRMARY.—On the 7th inst. the annual general meeting of the governors and friends of this charity was held. The report referred to the gratifying circumstance that the year's income showed an excess over expenditure of £1089 18*s.* 8*d.* The chairman, Mr. Alderman Brooksbank, stated that the Weekly Board had been able to effect an arrangement for an addition of two assistant physicians and two assistant surgeons to the medical staff. In future out-patients would be admitted, if necessary, every day in the week.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a meeting held on the 9th inst., Dr. Tatham was elected to represent the Association on the Council of the Metropolitan Society in London. Mr. Francis Vacher made some observations on the quality of the milk sold to the public in Birkenhead. Examination of samples of milk obtained from each of the 130 retail dealers in the town having been submitted to analysis, it was found that, though the milk generally was of good quality, in 21 cases it was either impure or not entire.

SMALL-POX AT SHEFFIELD.—A resolution has been passed by the Sheffield Borough Hospital Committee to purchase some leasehold premises adjoining the hospital, consisting of about 420 yards of land and five dwelling houses, for the purposes of providing increased accommodation in view of the prevailing epidemic of small-pox. Another resolution has also been carried strongly recommending the Council to acquire from 20 to 40 acres of land on or near the Redmires-road, on which to erect buildings or a building as a permanent hospital for small-pox and other infectious diseases.

A NEW DEPARTURE IN FRIENDLY SOCIETY ADMINISTRATION.—A new departure has, we understand, just been taken by the Foresters, the largest Friendly Society in existence, which, if generally followed, will largely supplement hospital work throughout the country. The Midland Courts of the Society have erected and opened a self-supporting convalescent home at Clent, where members who have suffered a long term of sickness may be sent free of charge, and without any burden being placed on charitable funds or public money. The movement promises to be one of the most successful which the Foresters have undertaken.

MEDICAL NOTES IN PARLIAMENT.

The Coal Mines Regulation Bill.

IN the House of Lords, on the 9th inst., the Coal Mines Regulation Bill was read a third time, and passed; and in the Commons, on Monday, the Lords amendment to the Bill was considered and agreed to, after the utterance of vehement protestations on the part of several members, in the course of which Mr. C. Graham was named by the Speaker, and had to withdraw from the House.

Navy Estimates.

In the House of Commons, on the 8th inst., on the vote of £75,400 for medicine, medical stores, &c., Dr. Tanner said the drugs in the naval hospitals and on board the ships were of an inferior quality. He also complained that the buying of perishable drugs in large quantities led to great waste, and stated that he had seen a quantity of "German" quinine, which was an inferior quality of the drug, on board the *Devastation*. Lord C. Beresford assured the hon. member that they took the greatest possible care to get drugs and medicines of the very best quality. He would, however, make inquiries with reference to what had fallen from the hon. gentleman. The vote was then agreed to.

Hospital at Salford.

On the 10th inst., in answer to Mr. Maclure, Mr. Ritchie said: "The guardians of the Salford Union propose to sell six or seven acres of land adjoining their infirmary at Hope to the Town Council of Salford for the erection of an infectious hospital. Representations have been made to the Local Government Board in opposition to the scheme. In a speech delivered when the present infirmary was opened, the then chairman of the board of guardians appears to have stated that there was an understanding that the guardians would not erect an infectious hospital on the site, but I am informed that there is no resolution of the guardians on the subject. I have instructed the inspector of the district to attend a meeting of the guardians and confer with them as to the proposed sale."

Vacant Grounds (Nuisance Prevention) Bill.

The second reading of this Bill, the object of which is to abate a nuisance in the shape of a fair held on the vacant ground adjoining Tottenham-court-road Chapel, was, on the motion of Mr. J. Rowlands, read a second time.

Coroners Bill.

On the motion for the second reading of this Bill, Mr. Conybeare commented on the arbitrary power possessed by coroners of excluding reporters from the court—a power which, he thought, ought not to be perpetuated.—The Attorney-General, however, replied that the question raised by the hon. member was foreign to the scope of the Bill, which was then read a second time. On Wednesday the Lords agreed to the amendments to the Bill made in the Lower House.

Trichinosis.

On Monday, Mr. C. Gray having adverted to the report that a large number of persons on the Continent were suffering from trichinosis from eating Hambro' bacon, and to the need of protective measures being taken on behalf of the inhabitants of the British Isles, the Secretary of the Board of Trade said no information of the matter had been received by the Board, and that the question relating to the importation of trichinous meat was one which came under the jurisdiction of the Customs.

Safety in Theatres.

In answer to Sir A. Borthwick, Mr. Matthews said the Government could not undertake at this period of the session to pass a Bill relating to securing the safety of the public in theatres. But he undertook that the Government would, at the earliest possible opportunity, offer practical suggestions to any theatrical manager who might think fit to adopt them, with a view to ensure safety in the practical details of the construction of such buildings.

Destitute Aliens.

On Tuesday, in answer to Captain Colomb, Mr. W. H. Smith said that Her Majesty's Government was fully alive to the importance of placing some restriction on the importation of destitute foreigners into this country, but there were many serious difficulties in the way of dealing with it, among them the right of asylum in this country. It would be unwise for him to say more than that the Government would give the matter their most serious consideration.

Births, Marriages, and Deaths.

BIRTHS.

CHARLES.—On the 8th inst., at Limehurst, Spring-grove, Isleworth, the wife of T. Edmondston Charles, M.D., F.R.C.P., Q.H.P., of a son.

MACKINNON.—On the 20th ult., at Bludaw, the wife of Francis Irvine MacKinnon, M.B., M.R.C.S. (Damascus), of a son.

MOORE.—On the 2nd inst., on board the P. and O. steamer *Parramatta*, from Aden, the wife of Surgeon R. R. H. Moore, Medical Staff, of a son, prematurely, stillborn. Indian papers please copy.

PERKINS.—On July 15th, at Patea, Taranaki, New Zealand, the wife of Alfred Temple Perkins, M.R.C.S.E., L.R.C.P. Ed., &c., of a daughter.

MARRIAGES.

DANIEL—NICHOLSON.—On the 7th inst., at Jesmond Church, Newcastle-on-Tyne, Frederic Edwin Daniel, Esq., M.R.C.S., L.R.C.P., L.M., of Brant Broughton, Lincs. (late of 32, North-road Durham), to Lucy, youngest daughter of the late Joshua Nicholson, Esq., of Newcastle-on-Tyne.

DAVIS—EATON.—On the 8th inst., at Sheffield, by special licence, Henry Davis, M.R.C.S., of Gower-street, London, eldest son of Dr. Henry P. Davis, of Upper Woburn-place, London, to Annie, eldest daughter of John Eaton, Esq., of Sharrow Bank, Sheffield.

HATTON—UDALL.—On the 3rd inst., at Remenham, George Stokes Hatton, M.D., of Newcastle-under-Lyme, Staffs, to Catherine Josephine, third surviving daughter of the late Thos. Udall, Esq., of Woodlands, Remenham, Berks.

WARD—ANDERSON.—On the 31st ult., at St. Mary's Church, Woolwich Lloyd Brereton Ward, Surgeon-Major, Army Medical Staff, to Fanny Louisa Kingsley, daughter of Col. Anderson, Commissariat and Transport Staff, Woolwich.

DEATHS.

BLOWER.—On the 30th ult., at Duke-place, Bedford, after an illness of twenty-eight years, William Blower, M.R.C.S., L.S.A., aged 84.

BROOKE.—On the 10th inst., at Milman-street, London, Charles Edward Brooke, M.R.C.S., of Oriel House, Scarborough, and of St. Bartholomew's Hospital, fourth son of the late William and Elizabeth Brooke, of Leeds, aged 30.

NORRY.—On the 7th inst., at Epsom, William Augustus Norry, M.B., M.R.C.S., aged 30.

PITCHER.—On Sept. 7th, 1886, at Southport, Arthur Henry Pitcher, L.S.A., eldest son of the late John Henry Pitcher, Proctor, of Doctors' Commons, in his 44th year. (Owing to a printer's error, the above announcement was inserted in our issue of last week "7th inst.," instead of Sept. 7th, 1886.)

ROGERS.—On the 2nd inst., at the Rowans, Woodside-park, North Finchley, Moses Rogers, J.P., late Deputy Inspector-General of Hospitals in India, aged 76.

SHEA.—On the 6th inst., at Reading, John Shea, M.D., aged 49.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BARRON, HUNTER JACKSON, M.D., C.M.Ed., L.R.C.P.Lond., M.R.C.S., has been appointed Divisional Surgeon to the Metropolitan Police S or Hampstead Division, vice Hochee, resigned.

BRODRICK, H. EDWARD, M.B., M.R.C.S., L.S.A., late Resident Clinical Assistant, East London Hospital for Children and Women, has been appointed Assistant Surgeon to the Liverpool Dispensaries.

CARR, WILLIAM, M.B., L.R.C.S.Ed., has been appointed Medical Officer to H. M. General Prison, Barlinnie, Glasgow.

DAVIES, J. B., M.B., C.M.Edin., has been appointed Resident Medical Officer to the Denbighshire and Flintshire Infirmary, Denbigh, vice John T. H. Davies, M.D., M.R.C.S., resigned.

GREENE, H. BERTRAM, M.R.C.S., L.K.Q.C.P.I., has been appointed Surgeon in the Service of the Royal Mail Steam Packet Company.

LOUDON, MARCUS MOORE, M.D., M.Ch.R.U.I., L.M., K.Q.C.P.I., has been appointed Medical Officer for the Workhouse and No. 1 District, and Public Vaccinator of the Mere Union, Wilts, vice H. P. Long, resigned.

PARK, DAVID SCOTT, L.R.C.P., F.R.C.S.Ed., has been reappointed Medical Officer of Health for the Beverley Borough of the Houghton-le-Spring Sanitary District.

PARKER, ALBANY J. ETHERINGTON, L.R.C.P. Ed., M.R.C.S., has been reappointed Medical Officer of Health for the South District, Houghton-le-Spring.

PHILLIPS, EDWARD B., L.R.C.P. Ed., M.R.C.S., L.S.A., J.P., has been reappointed Medical Officer of Health for the Rochford Rural Sanitary Authority, Essex.

SMYTH, R. V. B., M.A., M.D., B.S., has been appointed Medical Officer and Public Vaccinator for the Third District of the Barnet Union, vice Penn, resigned.

SOUTHEY, A. J., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Slough Urban Sanitary District.

SPROULE, R., M.D., has been appointed Medical Officer to the Gainsbro' Medical Friendly Society, vice Udale, resigned.

TURNER, CLIFFORD W., M.R.C.S., has been elected Resident Medical Officer to the General Infirmary, Leeds, vice T. W. Griffith, M.B., C.M., resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BATH ROYAL UNITED HOSPITAL.—House-Surgeon. £60 per annum, with board and lodging.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, and washing, but no salary.

CARDIFF CORPORATION.—Medical Officer of Health for the Urban and Port Sanitary Authorities. £100 per annum.

DEVON AND EXETER HOSPITAL.—House-Surgeon. Salary £120 per annum, increasing £10 a year until it reaches £150, with board and lodging.

EAST SUFFOLK HOSPITAL.—Honorary Physician.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge road, S.E.—Surgeon to out-patients.

FEMALE LOCK HOSPITAL, Harrow-road, W.—House-Surgeon. Salary £100 per annum, with board and lodging.

GREAT NORTHERN CENTRAL HOSPITAL, Caledonian-road, N.—Obstetric Physician.

HALIFAX INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. £50 per annum, with board and residence.

HORTON INFIRMARY, Banbury.—House-Surgeon and Dispenser. £60 per annum; with board and lodging.

LEAMINGTON AMALGAMATED FRIENDLY SOCIETIES MEDICAL ASSOCIATION.—Resident Medical Officer. Salary £200, with midwifery fees.

LIVERPOOL NORTHERN HOSPITAL.—Resident House-Surgeon's Assistant. No salary, but hospital practice and certificate of attendance, together with board and lodging.

LONDON TEMPERANCE HOSPITAL.—Registrar and Chloroformist. £50 per annum, non-resident.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Junior House-Physician. Also two House-Surgeons. Board, lodging, and washing.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road, S.E.—House-Surgeon. An honorarium of £70 per annum, with board and lodging.

ST. LUKE'S HOSPITAL.—Resident Clinical Assistant.

SHEFFIELD GENERAL INFIRMARY.—Two Assistant Physicians and two Assistant Surgeons.

TAUNTON UNION.—Medical Officer. Salary £75 per annum, with fees for midwifery of 10s. a case, and 2s. 6d. for lunatic returns.

TORBAY HOSPITAL AND PROVIDENT DISPENSARY, Torquay.—Junior House-Surgeon and Dispenser. Salary £90 per annum, with board, lodging, and attendance, and fees from pupils.

WESTRAY PAROCHIAL BOARD.—Medical Officer. Besides salary, a good general practice.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

"LEAVE HIS FEATHERS TO THE BIRD."

Mr. Punch, in his own way—and what an inimitable way it is, combining humanity with great wit and wisdom—has, in his current issue, another pathetic appeal to fashionable ladies to give, if possible, some thought to the cruelty entailed on some of the feathered tribe by the direction taken by their senseless love of extravagant adornment. Must these reiterated protests be for ever in vain?

* * * * * *

"Feathers deck the hat and bonnet,
Though the plumage seemeth fair,
Punch, whene'er he looks upon it,
Sees that slaughter in the air.
Many a fashion gives employment
Unto thousands needing bread;
This, to add to your enjoyment,
Means the dying and the dead.

Wear the hat, then, *sans* the feather,
English women, kind and true;
Birds enjoy the summer weather
And the sea as much as you.
There's the riband, silk, or jewel,
Fashion's whims are oft absurd;
This is execrably cruel;
Leave his feathers to the bird!"

A. E. Bendelack.—The statement should be accepted *cum grano*. The system referred to is as yet on its trial.

Mr. H. Francis.—Any surgeon would advise in the matter.

"SWEATING OF THE FEET."

To the Editors of THE LANCET.

SIRS,—Among the many remedies suggested for the cure of the above I do not see one which in my hands has always afforded relief. I mean the use of a foot-bath of nitro-hydrochloric acid. It need not be very strong, but just pleasantly acid. I am, Sirs, yours truly,

Sept. 13th, 1887. C. H., M.R.C.S.

THE INTERPRETATION OF PAIN.

A LETTER, having the Ulverston postmark, has arrived without name or address.

A Student should put his question to the Secretary of the Royal College of Surgeons.

THE STUDENTS' NUMBER: ADDENDA.

University of Cambridge.

THE following are the regulations for the examination in *Sanitary Science*:—An examination in so much of State medicine as is comprised in the functions of Officers of Health will be held in Cambridge on Tuesday, October 4th, and the three following days. Every candidate will be required to pay a fee of four guineas before admission to each part of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Walt-ham-sal, Cambridge. Candidates who desire to present themselves for examination in October next must send in their applications, and transmit the fees, to the Rev. Dr. Luard, Registrary, University of Cambridge, on or before Sept. 28th. Cheques should be crossed "Mortlock and Co." No fees can in any case be returned. The applications of candidates, whose names have not been on the register three years, should be accompanied by a certificate of birth, or other proof of age.

Post-graduate Course.—A course of instruction in laryngology, rhinology, and allied departments of medicine, for the benefit of gentlemen who have completed their medical curricula, will be commenced on the 20th inst. by Dr. Hunter Mackenzie, at the Eye, Ear, and Throat Hospital, Cambridge-street, Edinburgh. The course will extend over six weeks, and the fee will be £2 2s.

H. F. P. (Ostend).—For the required purpose there is no better treatise than the "Traité d'Hygiène Publique et Privée" of Bouchardat (8vo, pp. 1100, Felix Alcan, Paris, 1887). It is based on etiology, and this edition (the third) has been enlarged with notices of contagious diseases, cholera, rabies, &c. It ranks with the dictionaries of Littré and Robin, Delcambre, and Duval and Lereboullet for that skill in systematising so honourably characteristic of the French.

Mr. G. E. FitzGerald might apply to the Secretary of the Brussels Medical Graduates' Association, Dr. Pocock, 20, Golborne-road, Upper Westbourne-park.

RIGHTS OF UNREGISTERED PRACTITIONERS TO PRACTISE AND SIGN DEATH CERTIFICATES.

To the Editors of THE LANCET.

SIRS,—It appears from the following correspondence that it is lawful for unregistered medical practitioners to practise in this country with impunity, and sign death certificates, which are received by registrars and simply entered as uncertified without further action being taken against the person who signs the certificate. I have written to the Registrar-General respecting a case which has recently occurred in my district. As medical officer of health I received a return of deaths from the Registrar wherein one death was entered as due to dentition and bronchitis, and no medical man's name attached. On inquiry from the district registrar, he produced a death certificate signed by a person giving the titles "Physician and Surgeon U.S. America." This person's name is not on the Medical Register. On explaining this case to the Registrar-General, I received the enclosed reply.

I am, Sirs, yours faithfully,

Atherton, Aug. 30th, 1887. BENJ. MARSHALL, L.R.C.P., &c.

"General Register Office, Somerset House,
"London, 29th August, 1887.

"SIR,—I am directed by the Registrar-General to acknowledge the receipt of your letter of the 26th inst., and to inform you that registrars are instructed that whenever any certificate or written statement of the cause of death signed by an unregistered medical practitioner is produced to them by an informant they are to treat the statement as part of the particulars tendered by such informant, and not to insert in the column headed 'Cause of Death' in the Register the words 'certified by' and the name and qualifications of the medical man, as they do when a registered medical practitioner has certified the cause of death. It would seem that in the case you mention the registrar had acted in accordance with his instructions. I may add that the form of 'Medical Certificate of the Cause of Death' issued from this Department is intended solely for the use of *registered* medical practitioners, and should not be supplied to one who is not registered.—I am, Sir, your obedient servant,

"EDWARD WHITAKER, Chief Clerk.

"B. Marshall, Esq., L.R.C.P., &c., Medical Officer of Health,
Atherton, Manchester."

"A COURT PHYSICIAN BEHEADED."

THE *New York Medical Record* of Sept. 3rd prints the following:—"The Ameer of Afghanistan suffered not long ago from a boil on his neck, and sought relief at the hands of his court physician. The latter ordered some sort of a salve to bring the boil to a head. Unfortunately, the application caused the august patient considerable pain, and after a night of torture he sent for his physician and had him decapitated."

A. A. Turner should refer to the Charities Register and Digest, published by Longmans.

Miss M'Kenna.—We do not prescribe.

Digitized by Google

A DAY IN THE COUNTRY.

THE lay press is now, as is usual at this season of the year, teeming with appeals from philanthropic institutes and individuals for funds to enable children in poor and squalid districts to enjoy for a few hours the pleasures and advantages of fresh air and rural scenery. It needs no words of ours to impress upon the benevolently disposed the immense benefit conferred on the class referred to by such outings. Those who are accustomed to the sight of green fields, and to the exhilarating effects of pure and bracing air, can only by an effort realise the delight experienced by young people, who for perhaps three hundred and sixty-four days in the year are deprived of such enjoyment, when the opportunity is afforded them of roaming in country lanes and plucking wild flowers along the hedgerows of smiling meadows.

F. W. D. Evelyn.—Unless there has been some recent change in the medical regulations of San Francisco, any medical graduate or diplomate from a British university or licensing corporation can practise there.

G. P. has not enclosed his card.

CLIMATE AS A THERAPEUTIC AGENT IN PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I was rather surprised to read a letter in your issue of July 9th, 1887, recommending Aliwal North, Cape Colony, as a residential health resort for Europeans suffering from phthisis, supported, too, by the case of a clergyman who came out "to die," but returned home after twelve months' residence at this little town a "new man." Dr. Lindsay recommends "dry inland resorts," but Aliwal North through the greater portion of the year has a damp atmosphere. It is situated upon the banks of a large South African river, *alias* one of the large natural sewers. This river sometimes rises twenty or thirty feet in a few hours, and sinks again as quickly, leaving large or extensive muddy banks and muddy bottom, covered with all sorts of filth, which is exposed to a semi-tropical sun. The town is intersected with numerous open water furrows in almost every street, the water from the "hot spring" purges; the town is bounded upon two sides by a brackish, marshy plain, and on the opposite side by the Orange River. I think I have written sufficient to induce persons who are anxious to try South Africa to make further inquiries before incurring the expense of visiting Aliwal North, Cape Colony. My knowledge is gained by residence. After travelling over a large portion of South Africa, I have come to the conclusion that to "settle" anywhere, or in any town, village, or upon any farm—as Dr. Lindsay suggests—is a mistake; it is far better to move about, or, as the Boers say, "Treck! treck!" Of course, a pause here and there where special benefit is experienced is the only exception to this advice; but phthisical patients are generally obstinate and peculiar and rarely follow to the full the physician's instructions, and when in Africa they rush about to consult this medical man or that medical man, for the fame of each practitioner is ever upon the tongue of the people they meet, pouring into the ears the wonderful cures effected and the marvellous benefits to be gained by living here or there. Again, another drawback to South Africa is that every up-country resident is a physician or surgeon in his or her own way; these people are ever ready to prescribe root, herb, or other nostrum as a specific for the sufferer's disease; they generally have a long list of wonderful recoveries, to be shown to the unfortunate patient who is weak enough to submit to these "doctors." The climate of South Africa generally benefits phthisical cases on first arrival, and here and there are some good examples of permanent benefit; but, I repeat, to secure all the benefits this climate is capable of giving, you must travel, as a rule avoiding towns and villages; of course, using ordinary precautions against sudden changes in the weather; and travelling is very enjoyable even over African plains, and not expensive either.

I am, Sirs, yours truly,

South Africa, Aug. 11th. S. CARTWRIGHT-REED, M.D., F.R.C.P.Ed.

INFANTILE DIARRHŒA.

To the Editors of THE LANCET.

SIRS,—In your issue of Sept. 3rd you refer to Dr. Vaughan's work on the production of the poison tyro-toxicon in milk and cheese, and as to its frequent cause of choleraic diarrhœa in children. I have noticed that, in the summer months particularly, choleraic diarrhœa in children is most benefited by antiseptic treatment, and is often cured by changing from fresh to condensed milk. I have had a very large number of cases recently, and on inquiry found that the milk was got from dairies where the cows were fed on what is known as "draff," which is the refuse of breweries. This "draff" is kept in barrels for several days, and often when given to the cows has undergone a second fermentation. I have recommended, with success, that the children be fed on milk procured from the country where no "draff" is used; failing this, on condensed milk. The improvement is always most marked, and generally in a few days, with other appropriate treatment, recovery is complete. Boiling the milk, of course, improves it, but yet a complete change to healthy milk is more reasonable. Dr. Vaughan suggests that no milk be used where choleraic diarrhœa occurs; but I think if the precaution be taken which I have suggested there can be little danger from the use of the child's natural food. I am, Sirs, yours faithfully,

Hawick, Sept. 10th, 1887. JOHN R. HAMILTON, M.D.

THE ALT-SCHERBITZ.

IN the *International Record of Charities and Correction* for August Dr. Frederick Peterson gives a short description of the above asylum, in which the treatment of the insane is conducted on the village or cottage plan. The institution is, as some of our readers are aware, situated a few miles from Leipzig, and is, in the opinion of the writer, cleaner and better appointed than Gheel. All the occupations common to other establishments of the kind are in vogue here. Farming is, of course, the chief employment. But there are blacksmith, shoe, and carpenter shops, and, not the least interesting feature, a brick-yard. The patients have not only made all their own brick and tiles, but they sell large quantities. There is a large theatre in a separate building, where dramatic entertainments, concerts, &c., are given, joined in by both sexes. A bowling-alley is, of course, to be found here, as in most German asylums. A swimming-bath has also been constructed. "The freedom of the patients is very great, and there is no depressing aspect about the colony at all—nothing to constantly remind outsiders and insiders of the usual coercive nature of such institutions. All of the villas, both for men and women, and all of the dormitories connected with the dairy, the laundry, the kitchen, the workshops, and all of the houses of the little hamlet, have unlocked doors and unguarded windows. There are no bars on any windows in the whole establishment."

A Union Medical Officer would not be justified in refusing to act upon the order of the relieving officer. He has the opportunity afterwards of laying the case before his board if he considers he ought not to have been called upon to treat it.

Questio.—The arrangement mentioned would be unsatisfactory and, in a legal sense, unsound. We could not advise it as a permanent one.

Mr. W. J. Merlin (Sutton).—Mr. J. Offord, 67, George-street, Baker-street, W.

Dr. J. W. Fraser (Liverpool).—If possible, next week.

G. S.—The problem cannot be said to have as yet received a solution.

CASE OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—The fact of the following case being the fifth of the kind which I have treated with satisfactory results may perhaps entitle me to ask for the favour of its insertion in your columns.

On Aug. 30th, I was called in to attend Mrs. R——, aged forty-four; four children. On arrival, I found slight hæmorrhage, no pain. The os was dilated to the circumference of a shilling. Her history showed that the last period of menstruation was on Jan. 2nd; nothing unusual was noticed until the latter end of June, when there was slight hæmorrhage; again in July severe flooding came on, and continued for three days, and on this day, Aug. 30th, hæmorrhage had continued more or less severe from 4 A.M. until they sent for me at 10 A.M. I saw the patient again at 4 P.M. Hæmorrhage and pains increasing. At 6 P.M. her condition continuing nearly the same, I plugged the vagina. At 8 P.M. labour pains having increased, I removed the plug, and gradually dilated the os by digital distension. At 9 P.M. I gave a drachm of fluid extract of ergot. The hæmorrhage was now severe; pains only slight; os dilatable to the extent of a crown piece. My colleague, Dr. Follows, calling in at this moment to see me, kindly administered chloroform. Passing my hand into the uterus by gradually insinuating my fingers betwixt the uterine wall and the placenta, I ruptured the membranes, and, passing my hand along its abdominal surface, seized the child's feet, and brought them without the pelvis. Labour was completed in about ten minutes. The child was alive. The ergot given at 9 o'clock produced rapid contraction, and the placenta was expelled without difficulty. The after hæmorrhage was only slight. Examination of the placenta showed it to have had a central attachment. Mother and child are now doing well. I am, Sirs, yours respectfully,

Liverpool, Sept. 13th, 1887. JOHN OLDERSHAW, L.K.Q.C.P.I.

THE CONSUMPTION OF TEA AND COFFEE.

ACCORDING to the recently published report of the Commissioners of Customs the consumption of coffee in the United Kingdom during the last ten years has been, on the whole, decreasing. In the year 1877 the quantity of coffee consumed reached 32,236,016 lb., but in 1886 the total amount had fallen to 31,608,304 lb. It is noteworthy, however, that the use of chicory has not declined in corresponding ratio. On the other hand, the consumption of tea has largely increased in the last decade. Thus, in 1877 the quantity of tea consumed amounted to 151,274,852 lb., whilst in 886 the total had risen to 178,900,891 lb.

Enquirer.—A paper on the subject appeared in THE LANCET of Nov. 20th 1886.

Ambulance might with advantage consult Roberts' Illustrated Lectures, 1st Edition, published by Lewis, Gower-street.

Dr. W. W. Skinner (Paris).—We are unable to promise the insertion of the paper.

H. M. P.—Fuller particulars of the case should be given.

Clinical Lecture

ON A CASE OF

REMOVAL OF THE KIDNEY TOGETHER WITH BOTH OVARIES.

By FREDERICK TREVES, F.R.C.S.,

SURGEON TO AND LECTURER ON ANATOMY AT THE LONDON HOSPITAL.

GENTLEMEN,—I am drawing your attention to the case of a patient who is about to leave the hospital, not only on account of the clinical interest that surrounds the case, but also because it serves to illustrate certain points in the treatment of the subjects of abdominal operation.

The patient, a woman of twenty-six, was admitted in Jan. 1886, suffering from a tumour on the left side of the abdomen. She was thin and anæmic, and in bad health. She followed a somewhat laborious employment at a corset factory. She had been married for three years, but had never been pregnant. For six years she had suffered from profuse leucorrhœa. She was regular as regards menstruation, but at each period she experienced so much pain that she was compelled to rest for two or three days. She had been to more than one hospital about her pelvic troubles, but although she obtained some relief it was not long maintained. Two years ago she began to suffer from pain in the left side—a dull aching pain—that had persisted more or less ever since. A year ago she noticed a tumour in her left side. The swelling, she says, began "near the hip bone." It had grown slowly and steadily ever since.

This tumour, when it came to be examined, was evidently a tumour of the kidney. It was large; it reached from the ribs to the ilium; it extended to the right as far as the middle line; it was the seat of fluctuation. I should remind you that a renal tumour has the following characters:—1. It occupies the kidney region, filling up the loin between the last ribs and the iliac crest. (It should be noted that the hilus of the normal kidney lies about two inches from the middle line, and is opposite to the first lumbar spinous process.) 2. It is rounded everywhere; there is no sharp edge to be felt, and no notch, as in the spleen. 3. All is dull on percussion between the tumour and the spine, whereas in the case of a tumour of the spleen a resonant note can usually be brought out between the posterior margin of the mass and the spinous processes. 4. Unless the renal tumour is very large, it is possible to make clear its lower limits, and to demonstrate its freedom from connexion with the pelvic viscera. Its upper limits are not so readily made out. 5. The renal tumour, as a rule, does not descend on inspiration. 6. In front of it will be the colon. 7. If the tumour be innocent, it will not extend backwards, will not cause a protrusion of the loin. A cancer of the kidney may cause such a bulging in the lumbar region, and an abscess about the kidney will certainly have that character when it has attained to any dimensions.

In the case of this woman the tumour presented the general characters named. There were these special features, however: The lower extremity of the tumour could not be well defined. In the pelvis on the left side a rounded mass was to be felt on vaginal examination. It was soft and fixed, and it was not clear that it was quite separate from the abdominal tumour. This made one difficulty in the diagnosis. In the next place, the tumour was dull everywhere on percussion. There was no resonant bowel in front of it. The presence of the colon in front of a renal tumour is very usual, but it is not constant. When a certain disposition of the meso-colon exists, the bowel may lie entirely to the inner side of the mass. In the present patient I could feel crossing the front of the tumour from within outwards a movable cord, apparently about the width of the thumb. There was no difficulty in making it out. It felt solid, and was dull on percussion. It was the descending colon, empty and contracted. I have felt a precisely similar cord in another case of large renal tumour, and it proved on abdominal section to be the colon. I imagine that the nervous system of the intestine may have been disturbed by the tension of the bowel and mesentery, and so the tube retained in a contracted state. Neither in this case nor in the other named was the cord always to be felt, but there was never a tympanitic note in front of the tumour. In both patients the bowels acted very regularly.

No satisfactory diagnosis of the tumour was made before the operation. The fixed mass in the pelvis obscured the clinical picture. The abdominal tumour proved to be a very large hydronephrotic kidney, with scarcely any secreting tissue left; the pelvic growth was an adherent ovarian cyst. By hydronephrosis is meant a gross over-distension of the kidney by its own secretion. The trouble depends upon some mechanical obstruction to the escape of urine. The fault may be a congenital deformity of the renal hilus, the ureter, or the bladder. Most usually the obstruction is due to the pressure of a tumour on the ureter. Mr. Morris, in his most valuable work on the "Surgical Diseases of the Kidney," shows that by far the most common obstructing growth is a mass of pelvic cancer. In only four instances out of 142 examples of hydronephrosis collected by Mr. Morris was the obstructing cause an ovarian cyst. In the present case it is pretty clear that the ovarian tumour and the renal cyst stood in the relation of cause and effect.

There were two symptoms in the patient's case that pointed strongly to hydronephrosis. She stated that the tumour had at one time fluctuated in size, and that she occasionally passed large quantities of urine without apparent cause. These symptoms in hydronephrosis depend upon an occasional partial emptying of the distended cyst. During the time that the woman was under observation—about a month—the tumour never varied in size, nor did the amount of urine fluctuate beyond normal limits. Nothing abnormal was ever noticed in the urine. One other symptom, not uncommon in hydronephrosis, was absent—namely, frequent micturition. The tumour was irregularly rounded, was immovable, appeared to be of unequal density, gave a sense of fluctuation, and was not tender to the touch.

In the face of the doubts in the diagnosis, and the desirability that both the abdominal and pelvic tumours should be dealt with, I resolved to open the abdomen in the median line, in the region of the umbilicus. This I did on Feb. 2nd, 1886. I found the right kidney healthy and the peritoneum sound. The left renal region was occupied by a large hydronephrotic cyst. This was tapped, and then removed. The renal vessels and the ureter, having been clamped, were carefully and separately ligatured. The left ovary was the seat of a multilocular cyst the size of the fist. It was adherent to the left pelvic wall. The adhesions were readily divided, and the tumour was removed in the usual way. The right ovary was occupied by a similar multilocular cyst, the size of a hen's egg; it was free from adhesions, and was easily removed. The parietal wound was closed, and no drainage tube was employed. The patient has now recovered (after one vicissitude, to which I will allude), and is leaving the hospital, to all appearances, strong and well.

The operation in the present case must be regarded as quite exceptional so far as the kidney was concerned. The proper treatment of hydronephrosis is by lumbar nephrotomy. The cyst is exposed from the loin, is cut into and drained. If no kidney tissue is left, the resulting sinus may be induced to close, so far as my experience goes, by liberal injections of iodine. If any secreting tissue has survived, it may be removed by a subsequent operation at little risk, and the urinary fistula may thus be healed. The condition must be very rare in which abdominal incision would be required in hydronephrosis.

I might now mention a few of the circumstances that attend the opening of the abdomen. There is nothing special in the preparation of the patient, and there is no precaution required in ovariotomy that ought not to be taken in any other operation of any magnitude. The patient lies with his arms folded behind his back, and needs to be held by no kind of apparatus. All parts of the body are warmly covered; the lower limbs are enveloped with a small blanket, and are then packed, as it were, in a mackintosh. The ordinary mackintosh, with a hole, is used for the abdomen. Every trace of blanket or flannel should be covered up. In the gap between the thighs and the buttocks several sponges are packed, so that if any fluid runs down over the pubes it is at once absorbed. All the water used in the operation is carbolised; all the sponges are kept at a temperature of about 100° by the "sponge warmer." While the abdomen is actually open I use a carbolic spray. It is used partly at the dictate of a kind of surgical superstition and partly for this reason: the abdo-

Digitized by Google

minal walls are flaccid, and after the removal of a tumour, and during the introduction or withdrawal of the hand or sponge, considerable volumes of air must enter the abdomen, and it is well that the air should be as pure as possible.

With regard to the actual incision, it must be remembered that there is no linea alba below the umbilicus. Unless the muscles are separated by distension the knife will open one or other rectus sheath. The abdomen should be opened by precise, clean cuts; a director is an abomination, and the practice of deepening the wound with the fingers belongs to the surgery of past ages. Before the intra-abdominal operation is commenced a large sponge is placed in Douglas' pouch, and left there until the abdomen is ready to be closed. In removing the kidney the inner layer of the mesocolon will have to be divided. In that layer the vessels to the bowel run, and are very easily wounded. This especially applies to the inferior mesenteric vessels on the left side. In this and like operations a Trouvé's electric lamp is very useful, and saves much vague groping about within the peritoneum. In the process of removal it is scarcely possible to avoid actually tearing the serous membrane that covers the kidney. The rent made need not be closed, and the peritoneum appears to fall easily together. When much blood or fluid has escaped into the peritoneal cavity during the operation, it is much more readily got rid of by really washing out the abdomen than by the laborious and possibly damaging process of sponging. The assistant holds up the flaccid parietes by means of the wound edges, and the surgeon then pours in many pints of slightly carbolised water at a temperature of 100°. In this water the intestines can be rinsed. The water is allowed to flow off until it runs clear. A simple arrangement of the mackintosh allows it to drain away. The pelvis is then sponged out. Finally, the patient is slowly and carefully raised almost into a sitting posture, and the fluid that has collected among the intestines and in the pockets about the loins can gravitate into the pelvis, from which it is removed by sponging. The last sponge introduced should come out dry and clean.

In adjusting the incision the edges should be kept tight and parallel with one another by means of large blunt hooks inserted at either extremity of the wound, and held tightly by an assistant. The incision is then made, an even cut, and parts that were in contact before the operation come in contact again after the sutures have been completed. By means of the hooks, also, the parietes are drawn away from the viscera during the process of suturing. Upon the intestines lies a very thin flat sponge. It absorbs the last drops of blood that may come from the wound during the application of the sutures. It is drawn out just before the last two sutures are tied, and is thus made to wipe the peritoneal aspect of the wound. The only dressing I ever employ is a single large sponge well dusted with iodoform and secured over the wound by a gauze bandage. Before the bandage is applied, an extensive packing of loose soft gauze is made around the sponge, which is thus retained in position. The sponge exercises pressure upon the part, absorbs any discharge, and soon becomes dry. The gauze fills up the abdominal hollow and the depressions about the groins. Over all is a flannel binder that is accurately shaped to the body and is held firmly down by two pieces of flannel that pass along the perineum and around the thighs, and have either of their ends secured to the binder. If these thigh pieces are properly applied, it is hardly possible to work the finger beneath the binder in the region of the pubes. The wound is thus well protected in the most dangerous quarter. The sponge is easily cleaned after use, and may be employed over and over again. The dressing therefore is not expensive. This dressing is not disturbed until the sixth day, when it is removed and all the sutures are taken out. The wound is then supported by harelip strapping. This strapping is especially prepared, is fenestrated, and cut into strips that interdigitate. It keeps the wound together, but at the same time does not prevent any discharge from escaping, and any portion of the strapping can be readjusted without disturbing the rest. The sponge is replaced by iodoform gauze.

The general after treatment requires no comment, and is founded upon the simplest principles of therapeutics. On the second day warm fluids appear more acceptable than ice. After the removal of the kidney the patient sometimes remains low and dull, and is troubled with a somewhat persistent vomiting. The urine will generally be found in such a case to be of high specific gravity—1025 to 1040; and the symptoms probably are of renal origin. Under the circumstances, the greatest relief is afforded by a hot-air bath. This can be administered as the patient lies in bed without disturbing her in the least. It promotes profuse perspiration, and its use has been attended—in the few cases in which I have employed it—with most satisfactory results.

In the present instance another complication occurred on the fifth day: the patient developed symptoms of peritonitis. She had been very restless after the operation, and very sick. During the removal of the cyst some of its contents escaped into the peritoneal cavity, and may have caused the trouble. The abdomen, however, had been well flushed out. There had been no carboluria. The abdomen became distended; there was much vomiting, and a considerable amount of pain. The peritonitis was evidently attended by effusion. I imagine that peritonitis with effusion and pleurisy with effusion are pathologically the same thing, and are likely to be met by the same plan of treatment. Had the patient had a pleuritic effusion the fluid would have been withdrawn, and there appeared to be no reason why the peritoneal fluid should not be dealt with in like manner. The wound was therefore allowed to open at the lower part, and a very considerable quantity of clear serous fluid escaped. The upper part of the incision was most carefully supported by strapping. The wound was very frequently dressed with iodoform gauze. The fluid continued to ooze out in diminishing quantity for three days; it then ceased. By this time the patient, who had been fed by the rectum and had taken large quantities of brandy and opium, was free from urgent symptoms. The bowels were opened by enema on the ninth day. The wound was healed entirely by the twenty-first day. Six months have now elapsed since the operation, and the patient is up and walking about.

One small point remains. There is a risk after abdominal operations of a ventral hernia forming at the seat of the wound. To prevent this a strong abdominal belt is sometimes ordered. Such a belt I have never allowed a patient to wear. The ventral hernia is due to a weakening of the abdominal parietes. That wall is composed of muscular and aponeurotic tissues, and its strength will depend upon the state of development of the muscles. Muscle can only be made strong by use. If a belt be worn, the responsibility of supporting the viscera is thrown, not upon the abdominal muscles, but upon the instrument. The muscles are not encouraged to act. They are in the same position as the biceps when the arm is carried in a sling—wasting from disuse. To prevent a ventral hernia the patient should not be allowed to get up too soon. A month in bed is not an unreasonable time. She should not get up until the wound is sound. She may wear a light flannel binder for a few weeks after she is about again, but at the end of that time she should discard supports of all kinds. I am speaking, of course, of an ordinary case. With an abdominal wall already much weakened, loaded with fat, and pendulous, a substantial support may be needed.

The patient has reported herself a year after the operation. She is in good health and in actual work. The scar is sound, and shows no symptom of yielding.

THERAPEUTICAL VALUE OF THE MORE RECENT ADDITIONS TO THE GENITO-URINARY PHARMACOPŒIA.[1]

BY E. HURRY FENWICK, F.R.C.S.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL, SURGEON AND PATHOLOGIST TO ST. PETER'S HOSPITAL FOR URINARY DISEASES.

THREE years ago the Drug Committee of St. Peter's Hospital recast the Hospital Pharmacopœia. It would have been obviously unwise to have included any of the newer remedies without good evidence as to their real value. It would have been still more unwise to have rejected them altogether. I undertook, therefore, to investigate these "new drugs" systematically in the out-patient department, and to report subsequently upon them.[2] To make the inquiry thorough a large outlay of money would have been needed. This initial difficulty was overcome by the prompt generosity of Thos. Christy and Co., Lime-street, City. Those

[1] Abstract of two lectures delivered at St. Peter's Hospital.

[2] The histories of, and physiological experiments with, these drugs have been necessarily omitted.

Digitized by Google

well-known drug importers placed at my command for three years an unlimited supply of the new remedies which have been advocated for the treatment of genito-urinary disease. The following few grains of wheat remain after much winnowing.

Kola (Sterculia acuminata). — A powerful stimulant; contains 2·3 per cent. of caffeine, also theobromine. In the form of chocolate I found this drug to be of great value in tertiary syphilis, where large doses of potassium iodide have to be administered. The cases of syphilis in which the chocolate was first tried were often of the worst and most neglected type, being drawn from the neighbourhood of the London Docks. Later work has proved its value in the well-fed. Patients were able to take doses of 30 gr. to 60 gr. of the iodide without inconvenience as long as the kola was administered with it. It is now prepared in the form of a paste—"kolatina"—like cocoa paste, as it is found more effective in the liquid form. From 1 dr. to 2 dr. makes a breakfastcupful; where this is inconvenient, the stick kola-chocolate is eaten. Dose, 1 dr. to 2 dr.

Salix Niger (Black Willow).—A sexual sedative of decided value; useful in ovarian hyperæsthesia, also in prostatorrhœa, spermatorrhœa, excessive seminal emissions, and enforced continence. In the latter disorders its action is good, but inferior to potassium bromide. This is, however, somewhat counterbalanced by its non-depressant qualities. Dose, ½ dr. to 1 dr. Finding it of value in those wearisome cases of urethral neuralgias following gonorrhœa, I began to substitute soda salicylate for it. I was impressed by the relief this latter afforded. In cases of urethral pain in the adult, I first eliminate stone, stricture, urethral granulations, and over-acid urine, and then prescribe soda salicylate (5 gr. to 8 gr.), with a gratifying result.

Lycopodium clavatum.—The tincture is of real value in frequent micturition, irritable bladder, and cystospasmus, where such is not dependent upon actual disease or foreign body. It has been found useful in spasmodic retention of children. Dose, 15 m. to 1 dr. Note: White lycopodium is an inferior substitute, but still of some value. Dose, ½ dr. to 1 dr., between bread-and-butter. Yellow lycopodium is useless.

Kava Kava (Piper methysticum).—This drug is of benefit in pyelitis, cystitis (acute or chronic), and urethritis. It is inferior to copaiba, and sandal oil, but much more pleasant to take. It is of value when the oils are not tolerated. The inflammation seems to be increased at first. Fluid extract, ½ dr. to 1 dr. on a full stomach.

Stigmata maidis (Corn Silk). — Difficult to obtain at certain seasons, but of great value in pyelitis and renal colic. One case is especially worthy of notice. A patient who had suffered from renal colic and pyelitis for seventeen years was admitted into the hospital for exploration of the kidney. The patient was so relieved with corn silk that he refused operative interference. It is also of value in chronic or subacute cystitis, but in my hands it has failed in acute cystitis. Note: The fresh infusion is the best; dose, a wineglassful. Failing this, use the extract; dose, ½ dr. to 1 dr.

Papaw, Papyotin, Papaine (Carica papaya).—Of marked benefit in syphilitic ulcers of the tongue and throat, especially when mixed with cocaine. The surface of the ulcers and the white patches (secondary syphilis) rapidly clean and begin to skin over. Lozenges have been made by Messrs. Christy, which are most useful (papaine, ⅛ gr.; cocaine, ¼ gr.; potass. bicarb., ¼ gr.). In a girl of seven with severe syphilis of the mouth (after direct inoculation) the ulceration had resisted all applications for eight or nine months, and the child had wasted considerably. A few of these lozenges produced a marked effect, the ulcers healed, and the child rapidly fattened. Mix papaine with a small quantity of glycerine and water, so as to form a thin paste, add a little bicarbonate of potash, and brush ulcers with the same thrice daily. Whatever its position may be, as a digestive ferment papaine is worthy of trial as a preventive and reducer (?) of renal calculi. Dose for renal stone, 1 gr. to 3 gr., or more, in pill or powder; to be taken with meals.

Piché (Fabiana imbricata). — Of undoubted value in lithiasis and renal stone. One patient obtained so much relief from the hæmaturia and pain that he obtained the plant direct from Peru every mail, and made the infusion himself. In my hands it has failed in chronic cystitis. Dose, fluid extract, ½ dr. to 1 dr; infusion, a wineglassful.

Cocaine.—The fresh work with this drug is to be brought before the Medical Society. Routine work: Lithotrity in the feeble was performed with a 4 per cent. solution; small stones in the adult with a 20 per cent. solution. Internal urethrotomy needs a solution of 20 per cent., and any vesico-urethral instrumentation one of from 4 to 20 per cent.

Naphthaline ($C_{10}H_8$).—A derivative of benzol and allied to phenol. Given with benefit in fetid urine. The micrococci speedily disappear, and the urine becomes sweet. The large doses recommended (15 gr.) are unnecessary, and produce vomiting and abdominal pain. Dose 3 gr., cautiously increased. Note: Urine of patients taking naphthaline smells of phenol, and may remain exposed for some days without change.

Pine or Spruce Extract (Abies excelsa).—Has a slight diuretic action, and relieves renal pain unconnected with calculus. It is of use also in a bath, and as a liniment in gonorrhœal rheumatism. It is a pleasant vehicle for drugs in pyelitis and cystitis. Has proved of benefit in gleet. Dose, 1 dr. in water.

Ulexine (Ulex Europæus).—"A more powerful diuretic than sparteine or preparations of sarothamnus scoparius" (Gerrard). This is to be employed with caution in stricture. One patient with stricture of old standing, after taking a pill containing ⅓ gr., had temporary suppression of urine, vomiting, and fever.

Strophanthus (Kombè). — I believe there is a distinct future before caffeine, digitaline, and strophanthus as adjuvants to operations upon the vesico-urethral tract. We have sometimes to deal with partial or complete temporary suppression, and sometimes with rigors after operative interference or even instrumentation. Caffeine seems indicated to avert the former; strophanthus the latter. Again, if we have reason to anticipate sudden flooding of the renal vessels and consequent urinary fever as the result of an operation, then digitaline, from its power of controlling the renal circulation, is indicated. Our treatment, however, on these lines must go *pari passu* with our oncometric knowledge of drugs which affect the kidney circulation or the abdominal blood pressure. I believe strophanthus has power, worthy of further investigation, in controlling rigors. I employed it on the theoretical grounds that it increases cardiac power and general blood pressure. Five in-patients suffering from violent rigors after instrumentation, were treated with the tincture in doses of 5 m. after catheterisation. In no instance were rigors induced.

Chaulmiugra Oil (Oleum gynocardiæ). — Of value as a liniment in gonorrhœal rheumatism, osteocopic pain of syphilis. Its power is increased if it is mixed with lanoline. It has great influence upon some forms of adenitis, also in secondary syphilis. Dose 5 m. to 10 m. on a full stomach.

Hydrastis Canadensis (Golden Seal).—Of some use as an astringent vesico-urethral injection, checking mucous discharge; worthy of trial in some forms of prostatic engorgement and enlargement. Dose, 10 m.

Damiana (Turnera aphrodisiaca).—Good in some cases of diminished sexual power, where such does not depend upon organic disease. Often of use in melancholia and depression, if of genito-urinary origin.

Caroba (Jacaranda tomentosa). — Of some value in secondary and tertiary stages of syphilis. Dose, 1 dr.

THE BERGEON TREATMENT OF CONSUMPTION.

BY OWEN PRITCHARD, M.D.

I ENCLOSE notes of two cases of phthisis treated in private practice by gaseous injections into the rectum, after the plan advocated by Dr. Bergeon. All the details of this treatment being so lucidly and minutely described by Dr. Burney Yeo in his lecture published in THE LANCET of April 16th, it would be an entire waste of time to enter into the particulars of it. I would only say that, having obtained the necessary apparatus, I endeavoured as nearly as possible to follow the directions so explicitly given by Dr. Yeo.

CASE 1.—Mrs. E——, aged sixty (her usual weight 10 st. 5 lb.), says that in July last year she began to lose strength, had a slight cough, her appetite became indifferent, and she noticed that she was losing flesh. After a fortnight at Hastings she was much improved, but on her return

Digitized by Google

to London about the end of August she soon began to lose flesh again, and her cough became very troublesome, with a persistent sore throat. She attended the Throat Hospital until the end of December, gradually getting weaker. Becoming very uneasy, she tried one or two other institutions; but during January, February, March, and April she was still rapidly losing flesh, the cough was much more troublesome, the expectoration thicker and more profuse, and the night sweats exceedingly severe. In the beginning of June, when I first saw her, she weighed 8 st. 5 lb., having lost 2 st. from her usual weight in eight or nine months. She complained so much of the cough and night sweats that she declared she never could sleep more than half an hour at a time, and even this amount of sleep was much disturbed by frightful dreams, such as tumbling over cliffs, fancying herself fighting bulls or tigers, or assisting to put out fires, &c. On examination, her left lung was, as far as I was able to judge, normal, but the right was quite solid from apex to base, and a portion about midway between the nipple and axilla had actually broken down into a cavity. Her temperature varied from 101° to 103°. The expectoration was purulent, very copious, and full of bacilli. The first operation was performed on June 9th, and repeated each day from then until now. For the production of the sulphuretted hydrogen a solution of sodium sulphide and caustic soda similar to that advised by Dr. Yeo was used, and the sulphuretted hydrogen liberated by throwing in a small quantity of tartaric acid. Now, as is the case with nearly all the victims of consumption, one was not at all surprised to find this patient declaring herself much better at the end of the first week of a new treatment. She, however, knew exactly in what way she was better. Her cough, she said, was easier, and the expectoration somewhat diminished; the night sweats had almost ceased to trouble her; but, above all, her sleep had returned and the frightful dreams had gone, and she could now, she said, sleep for four hours right off, and then only wake up to cough and bring away the accumulated phlegm, and turn over and go to sleep again. Several weeks thus went on, the patient assuring herself and everybody around her that she was daily improving. She got up, she said, every morning refreshed after her beautiful night's sleep. Her temperature, however, still kept up, and the tubercle bacilli remained in the expectoration as numerous and robust as ever, but the amount of expectoration diminished, and for many weeks she continued to lose weight rapidly. Her temperature for some weeks past has been considerably lower, seldom over 100°, and she has in the last week or two actually gained a little in weight. A table of her weight with dates as taken is as follows:—June 9th, 8 st. 5 lb. 14 oz.; June 24th, 8 st. 3 lb. 8 oz.; July 12th, 8 st. 1 lb.; July 22nd, 8 st. 10 oz.; Aug. 4th, 7 st. 13 lb. 14 oz.; Aug. 15th, 8 st.; Aug. 22nd, 8 st. 1 lb. 8 oz.; Aug. 29th, 8 st. 3 lb. From the foregoing it will be seen that she was losing very rapidly at the beginning of her treatment, but her loss gradually became less marked, and for the last three weeks she has actually gained some pounds in weight.

CASE 2.—Mrs. T——, aged thirty-four. Last October she had a sharp attack of bronchitis, from which she has never quite recovered, a troublesome cough remaining through the winter. During the first four or five months of this year she had been getting thinner, her appetite being very bad and her night's rest greatly disturbed by the cough and the severe night sweats. When I saw her in the beginning of May she was considerably emaciated; temperature 99° to 100°; moist râles over both apices; right apex slightly dull on percussion; expectoration was abundant; breathing short and asthmatic; her face livid. On May 28th her weight was 8 st. 10 lb., when the first operation was performed, and continued daily until July 30th. After the first week her cough was much improved, and, the night sweats having disappeared entirely, she slept well, her breathing was quite free, and consequently the colour of her face was much healthier. But, like Mrs. E——, her great pride was that she slept so much better, being undisturbed by cough and night sweats. During the first four weeks of treatment she lost 3 lb. in weight, but during the last five weeks she gained 6 lb., and left town for Devonshire in the beginning of August, and I have just received information from her that from August 3rd to 19th she had gained another 3 lb.

These cases are, of course, at present incomplete, but they seem to me as far as they go to prove very distinctly that this treatment, even if it does not positively cure, very greatly retards the progress of the disease, and almost entirely removes its most trying symptoms.

Southwick-street, W.

CASE OF SUPPURATIVE PYLEPHLEBITIS AND ULCER OF THE VERMIFORM APPENDIX.

BY D. COLQUHOUN, M.D., M.R.C.P. LOND.,
LECTURER ON THE PRACTICE OF MEDICINE, OTAGO UNIVERSITY, NEW ZEALAND.

JAS. D——, aged forty-eight years, was seen by me first on Dec. 22nd, 1886, in consultation with Dr. A. J. Fergusson. He had then been ill for about seven days. He was a man of exceptionally good physique, had never had any serious illness, had suffered twice from attacks of ague in Canada twenty years before, but, except that he had a somewhat irritable digestive system, his health had always been very good. His habits were temperate and regular. On Dec. 11th he had dined more freely than usual, and had been exposed a good deal on a cold and wet day. On the 14th he felt a good deal of pain in the abdomen, and was slightly sick. The weather at this time was unusually cold, and he believed he had taken a chill. On the 17th he began to have a series of shivering fits, "exactly like his ague attacks twenty years before," and recurring at regular intervals of about eleven hours. In about twenty-four or thirty-six hours jaundice set in. The bowels were freely opened, and the motions appeared at first normal in character.

When I saw the man on Dec. 22nd the jaundice was very deep. He was in a state of great mental and physical depression. Temperature 101·4°; pulse 96, fairly regular. He had had one attack of epistaxis, and there was a slight expectoration of mucus tinged with blood, not unlike the rusty sputum of pneumonia. The heart sounds were normal, and the lungs seemed to be quite healthy. The abdomen was distended with flatulence; there was no pain complained of in any region, but deep pressure over the region of the gall-bladder seemed to give rise to some discomfort. Owing to the flatulent distension the liver dulness was less than normal. The bowels were rather constipated, and the stools seen at this date were apparently quite devoid of bile. The urine was deeply tinged with bile pigment. On the 24th he was much weaker; the temperature in the evening reached 104° and he had had several attacks of extreme prostration, especially occurring in the early morning. During these attacks the pulse became intermittent and feeble. On the 25th he was distinctly delirious. The weakness was increasing, but the pulse remained regular—96 to 100. The stools contained no bile, and the urine was very deeply coloured with bile. On the 26th there was a very slight trace of bile in one stool. Jaundice continued intense. He was pretty constantly in a state of low muttering delirium, or sleeping uneasily by fits and starts. There was no vomiting. At 1.10 P.M. the pulse was 96; temperature 98·4°; respiration 36. The meteorism was more marked than before. On the 27th there was some vomiting after taking extra nourishment which had not been ordered, but otherwise his condition was unaltered. The feebleness and delirium became more marked, and on the 28th he passed into a state of coma and died in the evening.

A post-mortem examination was made two days later. The body was well nourished. The abdomen was distended by gas in the intestines. The liver was normal as to size, but, on cutting into it, was found to be studded with small points of purulent deposit. The portal vein and its radicles were filled with greyish pus, the points above noted being the vessels seen in transverse sections. The gall-bladder was nearly empty, and it and the gall-duct seemed normal. The intestines were congested in parts. In the stomach were a few small inflamed patches near the pyloric orifice, but, on tracing the intestine down to the cæcum, no ulceration could be found to account for the suppuration in the portal vein. Round the vermiform appendix, however, a wormy mass could be felt, and on removing this with the cæcum and vermiform appendix, it was found to consist of apparently a mass of congested or strangulated tissue. On opening the cæcum, no ulcer could be seen there; but on

Digitized by Google

laying open the vermiform appendix, it was found to be ulcerated for about an inch from the entrance to the cæcum; the ulcer became continuous with the outside congested mass, which was composed mainly of inflamed veins. The mesenteric veins were not noticeably enlarged. Only these parts of the body were examined.

Remarks.—The post-mortem examination cleared up what had been a very doubtful case during life. The sequence of events seemed then plain enough. Some foreign matter—not detected post mortem—gave rise to an ulcer of the vermiform appendix; this was followed by a local phlebitis, and that again by phlebitis of the portal vein by embolism. All the radicles of the portal vein were more or less involved, but circulation through it was free enough, as there was no ascites or other sign of impeded portal circulation. The jaundice may have arisen from retention of bile elements in the blood, or bile may have been secreted as usual by the liver cells and immediately reabsorbed. The gall-bladder was empty, and little or no bile had found its way for some time into the intestine. Very little notice seems to have been taken of this condition by British writers. It is not mentioned at all in most of the various English works on medicine. In Quain's Dictionary there is a brief notice of the disease, and a passing reference to it in the article on Jaundice. I have not been able to find any cases reported in THE LANCET or the *British Medical Journal* of the last eight or nine years; and yet the condition cannot be very uncommon. There is an account of it in Frerichs' "Diseases of the Liver," derived from twenty-five reported cases. In Ziemssen there is a very large number of references given to cases of suppurative pylephlebitis, mostly from German sources, but partly also from English and French; and in Pepper's "Practical Medicine" the disease is spoken of as a common one. Concerning the diagnosis of the disease there seems to be a good deal of difference of opinion. Von Schueppel, writing in Ziemssen's Encyclopædia, says: "Some consider it a rare stroke of good fortune to recognise the disease; others maintain that nothing is simpler and easier than the diagnosis of suppurative pylephlebitis." Frerichs says that jaundice occurs in three-fourths of the cases of pylephlebitis. Dr. Bartholow, writing in Pepper's work, says that three-fourths of the cases are free from jaundice. The most important factors upon which the diagnosis should be based are stated by von Schueppel to be the following, or some of them. 1. The presence of an affection which we know may act as a starting point of pylephlebitis. 2. Pain at the epigastrium or any situation in which the pylephlebitis may start. 3. Rigors at irregular intervals, with high temperature, and *during the intermissions* abnormally high temperature. 4. Recent painful enlargement of the liver. 5. Considerable enlargement of the spleen. 6. Jaundice, with biliary diarrhœa. 7. Rapid emaciation and loss of power. 8. The occasional development of diffuse peritonitis and typhoid symptoms in the later stages of the disease. Comparing these diagnostic factors with the history of the case reported above, hardly any of them could be said to be present. There were no antecedent or existing symptoms pointing to the presence of any exciting cause of pylephlebitis. There was some diffuse pain all over the abdomen early in the disease, and tenderness on pressure about the portal fissure, but no local pain was complained of. The rigors occurred pretty regularly at first, then were replaced apparently by attacks of collapse, and the temperature was not abnormal in the interval. The liver was neither enlarged nor painful, nor could the spleen be traced owing to the flatulent distension of the intestines. The jaundice was not accompanied with biliary diarrhœa, there was little or no emaciation, and there was no peritonitis. In this case the symptoms which seemed most characteristic were the quick interference with the functions of the liver, the jaundice, the biliary toxæmia, and the ague-like rigors, occurring in a previously strong and healthy man, not exposed to any malarious or other poisonous agencies.

At the recent examination at Aldershot, at the end of the summer course, for medical officers of the army, on the subjects of Military Law, Bearer Column Organisation and Drill, the first, second, fourth, and sixth places in order of merit were assigned to Volunteer medical officers. The first place was taken by Surgeon W. Collingridge, M.D., 3rd (Woolwich) Division, Volunteer Medical Staff Corps; Surgeon J. Reece, of the London Division, being second.

REMARKS ON ALGIERS AND ITS CLIMATE.

BY T. D. SAVILL, M.D. LOND., M.R.C.P.

AT a time of year when so many people are planning on taking their annual holiday, in pursuit of either health or pleasure, it occurred to the writer that a few remarks on Algiers and its climate would be appropriate to the season, and acceptable to the readers of THE LANCET. The facts to be mentioned are based chiefly on information gained during the greater part of three winters which were spent in or near the town. But there are, perhaps, few things more difficult than to give a strictly true and impartial account of a health resort. The impressions of a place which each one forms so much depend on the kind of the season he encounters there, his comforts and immediate surroundings, and on his very mood of mind, that it is not surprising if two descriptions of the same place differ as widely as sunshine and shade. The only way to get at the approximate truth about a climate is by the examination of a series of accurate and carefully recorded meteorological observations extending over many years, combined with a careful study of the vegetation and physical aspects. There are some of the first-named records scattered through the numbers of the *Journal de Médecine et de Pharmacie d'Alger*, made by M. MacCarthy, the librarian of the Musée Bibliothèque, through whose kindness I have been able to procure them.

The town of Algiers is situated on the western side of a wide, shallow bay, and its general aspect is east-south-east. It is flanked on the west and north-west by hills of the Sahel range, which reach an elevation of 1000 to 1500 feet, and it is well protected on all sides except east and south-east. It may be mentioned, in passing, that the winds coming from these directions are generally mild. The north-west wind is the one to be dreaded, for it is fierce, cold, and wet. The town itself is built up the eastern side of one of the Sahel hills. The more modern part is situated along the sea coast; and the old town, with its narrow streets and white windowless houses, just as it was in the days when it was the home of the Barbary pirates, stretches tier above tier to the top of the hill, at the summit of which is the Kasbah or citadel. The beautiful suburb of Mustapha Supérieur, consisting of villas scattered along the wooded sides of little hills, and almost entirely appropriated by English visitors, lies to the south. The old part of the town retains its Oriental characters in a marked degree. The houses, which are always built round a central court, with no windows outside, and a flat roof, are packed close together, and the streets are so narrow as only to allow sufficient space for two pedestrians to pass.

The natives of both sexes also preserve their Arab garb, and until lately did not mix very freely with their conquerors, the French. The dress of the women out of doors consists of a long white shawl of delicate texture, covering the head and shoulders, gipsy fashion; a *yashmák*, concealing the lower half of the face; and loose white pantaloons, which cover their nether extremities to the ankle. The Arab is characterised by his olive-brown skin, black hair and eyes, fine physique (generally speaking), and a remarkably grave and dignified bearing. His dress is all white, and those who live in towns wear a turban of white linen, loose hooded cloak or *bournous*, beneath which their bare or white-stockinged legs appear, terminating in shoes of ordinary pattern. They are an interesting race, and it is difficult to account for the gradual dying out of a people that still present so fine a physique. In addition to natives, Maltese, and French, there is a large Jewish population, who still wear the ancient Jewish garb. Mixed altogether, these different costumes have a picturesque appearance, which is very striking to the eye of a stranger. And thus it happens that there are three distinct Sabbaths observed in the town: the Mohammedan on Friday, when the women repair to the cemeteries; the Jewish on Saturday, when quite half the shops in the town are shut; and the Christian Sunday. An interesting ceremony is conducted every Sunday at Nôtre Dame d'Afrique, situated on the highest hill near the town, where the burial service is read over the sea for all mariners who may have been drowned during the preceding week.

Digitized by Google

There are several hotels in the town, but no one in pursuit of health or pleasure should stay there, for it is neither sanitary nor agreeable.

The vegetation around Algiers is very luxuriant, and leads one to expect a heavy annual rainfall. The hedgerows are formed of cactus or prickly pear, interspersed with the thick-leaved aloe, whose tall flower-stems stand up like sentinels. Palms of many varieties, and the broad-leaved banana tree, with its huge spiral bunches, flourish in the very precincts of the town. Roses bloom in January, and green peas are then in season. In the shaded nooks of Mustapha the maidenhair fern grows wild, and the mountains on the opposite side of the plane are covered with hardy lentiscus and olive trees. Between the hills along the shore, the plane of the Metidja extends for sixty miles from east to west. Here grapes, oranges, and lemons are cultivated with success. The latter are of much value as climatic indicators, for the blossom does not survive a single degree of frost. The eucalyptus tree does exceedingly well under the combined influences of high temperature and heavy rainfall. In the exhibition of native industries there is the trunk of a tree thirty feet long, which took, so it is stated, only three years to grow.

The soil on which Algiers is built is mainly gravel and chalk. In the Metidja and the planes generally of Algeria it is clay, and on the high table land it consists of loam. I have often heard it said by those who have been there, that the appearance and arrangement of this latter is very like the gold fields of Australia, and is very suggestive of gold. Earthquakes occur from time to time in the interior, but are never of great severity.

The climate of Algiers is essentially one for the winter months. From the middle of October to the middle or end of April is the most agreeable time to stay. The mosquitoes are troublesome until the former date, but for those who like moderately warm weather May is an exceedingly agreeable month. I have heard of consumptive invalids deriving great benefit by staying for two winter seasons and through the intervening summer, but the heat of July and August must be very trying. The following are the mean temperatures (reduced to the Fahrenheit scale) of the months throughout the year 1884, which, after an examination of the records, I selected as a sample:[1] January, 53·2°; February, 58·1°; March, 58·1°; April, 60·1°; May, 65·8°; June, 67·5°; July, 75·2°; August, 77·7°; September, 76·8°; October, 66·9°; November, 59·7°; December, 56·4°. The mean temperature of the six winter months of this year was 58·7°, that of the summer 70·5°. The average winter temperature (October to March), reckoned from the Government observations in the thirteen years 1865 to 1877, was 58·4° F. This is a temperature which will compare very favourably with most of the winter health resorts on the other side of the Mediterranean.

In all countries where clear atmospheres and cloudless skies prevail, the rapid radiation of heat from the earth immediately after the sun goes down gives rise to a sudden chilling of the air and to heavy dews; and since Algiers is no exception to this rule, invalids should avoid being out at this time, although I believe, from the observations which I made, that the fall of the mercury rarely exceeds 8° or 10° F.

There are no records of the number of hours of bright sunshine, but the amount of this is one of the most noticeable features of the climate. In the months of November and December, 1880, I counted forty-seven consecutive fine days. Rain fell during this time, but it came at night, and therefore did not hinder invalids from going out. In 1884 the number of days on which no rain at all fell was as follows—January, 20; February, 20; March, 14; April, 14; May, 26; June, 24; July, 28; August, 28; September, 20; October, 18; November, 9; December, 14. Total of six winter months, 95; total of six summer months, 140. Besides the days on which no rain fell, there were others when it fell at night, or for such a short time as not to prevent invalids from being out of doors. The rainfall of that year was 22·9 inches in winter and 7·4 inches in summer.[2] No doubt this is large as compared with some places. It is only what is to be expected from an examination of the vegetation. Two facts, however, should be remembered in relation to this—firstly, that it frequently rains in the night; and secondly, that the showers are mostly very heavy while they last. The percentage humidity during the year 1884 was as follows—January 73, February 66, March 72, April 65, May 69, June 70, July 71, August 71, September 71, October 70, November 76, December 75, saturation being represented by 100. The mean of the winter months was 72 per cent., and of the summer 69 per cent. For the sake of comparison it may be mentioned that the mean annual humidity recorded at the Greenwich Observatory is 87 per cent.

One may say, then, of the winter climate of Algiers that it is mild, equable, and of medium dryness; that there are usually a large number of fine days, and days on which the invalid can be out of doors; and that the proximity of the sea on the north imparts to it a bracing character, which is hardly to be expected after an examination of the rainfall and percentage humidity.

The class of disease for which Algiers is most suited is undoubtedly lung affections, and especially phthisis. It is not within the scope of this brief note to discuss the relative advantages of high, dry, mountain air, and such climates as the one now under consideration, in the treatment of pulmonary tuberculosis.[3] That this disease, when not too advanced, is capable of being arrested and ameliorated by residence under favourable conditions at Algiers there is ample testimony to show. Dr. Feuillet was deputed some years ago to make an official inquiry into the relative frequency of phthisis in Algeria compared with that in Europe, and in 1874 he published the results of his observations at considerable length.[4] The conclusion arrived at was that "deaths from phthisis in Algeria are but a fifth part as common in Algeria as in Europe." This was derived from figures which included cases occurring both amongst Europeans (many of which were imported) and amongst natives. His observations also revealed three facts, which he offers (p. 140) in explanation of the above statement: "1. That phthisis *originating* in Algeria is rare. 2. That the disease, especially when imported, is cured in its early stages, without medical intervention, by the sole action of the climate; and even if it be a little more advanced, it is still cured or ameliorated by the same means. 3. The chances of abolishing hereditary tuberculosis are almost certain when the children are placed under such favourable climatic conditions from infancy upwards."

Persons with other diseases of the lungs—chronic bronchitis, emphysema, and asthma—also derive marked benefit from passing the winter at Algiers; but they should not attempt the sea voyage when the heart is extensively deranged and weakened.

The climate of Algiers is not suitable to the treatment of rheumatism in any form; and I have never seen a case which derived the slightest benefit there. The hot baths at Hamman R'Irha, situated among the Lesser Atlas Mountains, sixty miles from Algiers, and which are described elsewhere,[5] are eminently suited to the treatment of this complaint. The rheumatic invalid should never allow himself to be tempted by the society and attractions of Algiers to pause for more than two days in his transit to the less gay but more favourable spot. Those who go into the interior should avoid valleys not well under cultivation, since a mild form of ague is sometimes incurred in such districts.

The clothing best adapted to this climate is that worn during an average English spring. Invalids should always be provided with flannel underclothing. The amusements consist of riding and driving out of doors, tennis on tufa courts, and society. There is a large number of English winter residents, and, thanks to the geniality of the English consul, Sir Robert Playfair, there is much pleasant social intercourse amongst them. Perhaps it is the sea voyage of thirty to thirty-six hours across the Mediterranean which deters the more fashionable pleasure seekers from frequenting Algiers, and causes them to halt at more easily accessible places like Nice and Cannes. It is not generally a disagreeable sea voyage, but the only way to shorten it is by crossing from Carthagena in Spain to Oran; but travelling by railway from the latter place to Algiers is a slow and wearisome journey, albeit through a country which is one of the granaries of the world.

Paddington Infirmary, W.

CASES OF BONE DISEASE AFTER SMALL-POX IN YOUNG CHILDREN.

BY ARTHUR NEVE, F.R.C.S.E., &c.

As far as I can judge from the limited statistics available, over 75 per cent. of the population of Kashmir die in childhood from small-pox. Some of the sequelæ, such as total or partial opacity of the cornea, or destruction of the eyeball, are daily seen in our consulting-room. These are also to be seen in England, but less familiar there are the acute bone and joint affections of which I append a few examples. Cases 2, 3, and 4 occurred during the spring of this year, and the first is published with them because it is probably almost unique:—

CASE 1. *Disease of both elbow and one wrist joint; simultaneous excisions; cure.*—J——, a boy, aged three, suffered from small-pox during September, 1885. He was seen at the Mission Hospital on November 5th. Both elbow joints and the right wrist were swollen and freely discharging pus. The abscesses had burst a month previously. The child appeared strong considering the abundance of the discharge. On the same day, with full Listerian precautions, I excised both elbow joints, and freely gouged the wrist, in which the mischief was centred in the lower epiphysis of the radius. The parts were dressed on the 6th, the 9th, and the 11th. On the 9th the left elbow was found completely healed, the skin over the right elbow ulcerating a little, and the wrist wound granulating rapidly, with scarcely any suppuration. On the 19th the wounds were healed. A small abscess in the right elbow burst on December 1st, and on the 10th the child left the hospital cured, with very good movement of the arms, and having picked up strength completely.

CASE 2. *Complete necrosis of ulna; resection; cure.*—S——, a child, aged one year and a half, had small-pox in February, 1887. A month later an abscess formed behind the elbow, which burst and discharged, at first abundantly, then less. On May 18th he fell, and bone protruded from the wound. On the same day he was brought to the hospital. His whole forearm was swollen and red, and from an aperture at the back a portion of dry smooth bone, apparently the olecranon, projected. Under chloroform this was seized with necrosis forceps, the skin opening slightly enlarged, and a few adhesions separated; the whole diaphysis of the ulna was then removed. An opening was made near the wrist through the skin and through a thin case of cartilage which completely surrounded the site of the shaft. The lower epiphysis was covered with soft granulations. The elbow joint appeared unaffected. A drainage tube was drawn through the tubular hollow and dressings applied. On May 28th the drain was removed, when the cavity rapidly closed with granulations, and the limb promised to be in no way impaired in its usefulness.

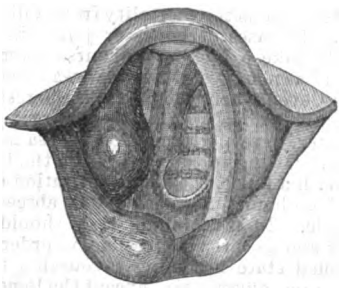
CASE 3. *Necrosis of scapula; resection; cure.*—A——, a well-nourished child, six months old, was brought to the hospital on April 22nd with a sinus in front of the left armpit, from which watery pus was discharging. An abscess had first formed some weeks previously after an attack of small-pox. The scapula was enlarged, and the sinus led towards it. Chloroform was at once administered, the sinus incised sufficiently to admit the finger, and another incision made at the lower angle of the scapula. The state of things was peculiar. The finger passed inside a distended shell of semi-ossified cartilage; some thin fragments of similar material were loose in the cavity or partially adherent to the walls; and some sharp spicules projected inwards from the spine and neck. With a gouge as much as possible was removed, leaving merely the spine and neck, with the thin shell. For the first few days the cavity was well syringed out; on the 27th the drainage tube was removed from the posterior opening, which had nearly closed. There was a good deal of reaction. By the end of April the whole cavity was filled and distended with granulations, from which there was a slight sero-purulent discharge. On May 12th the wounds were healed, except for slight oozing from the sinus in the axilla; but a slight erysipelatous rash appeared, which extended in an irregular manner for a day or two, disappearing from one part to begin in another. On May 16th the parents took the child home, considering it cured.

CASE 4. *Acute suppuration of shoulder joint; incision and drainage; cure.*—A thin, weakly boy, about six years old, was brought with a large fluctuating swelling over the shoulder. He was only recently convalescent from small-pox. The swelling was not very tense, painful, or red. It was of a fortnight's duration. On April 1st the abscess was opened by a free incision, and the shoulder joint, with which it communicated, well washed out with mercury lotion, and a drainage tube inserted. He did not remain in hospital, but was brought on four or five occasions to have the wound dressed. On about the seventh day the drainage tube was found to have come out; it was not replaced, and when last seen the wound was healed and the boy gaining flesh.

The foregoing are fairly typical examples of a class of cases common wherever vaccination is not practised. So common are they here that bleeding is universally practised by the native hakims during the later stages of small-pox, with the hope of preventing the formation of abscesses! This practice doubtless swells the mortality from a disease always so formidable. Diseases of bones or joints in very young children usually take a favourable course after operation; and if the child has not been otherwise weakened by starvation or bleeding, even when the disease is the result of small-pox, the prognosis is hopeful. In Case 1 three operations of a grave character were performed on the same individual simultaneously. Owing to the softness of the bones, which could be cut with a knife, the whole operation did not take more than half an hour. Post-small-pox abscesses are frequently multiple. In my opinion they should be opened simultaneously and as early as possible, in order to allow of the constitutional state becoming favourable to cure. In Case 2 the ulna came away entire, except the lower epiphysis. The upper epiphysis is at the extreme tip of the olecranon, and was not separated. The curious point is how the joint should have escaped participating in the inflammatory process. Whatever part the epiphyses may play in primary inflammatory processes (and this is as yet not very clear), they, as a rule, play a very important part in limiting necrosis to the diaphysis of bones, as Cases 2 and 3 illustrate—a fact of which surgeons should avail themselves in the pre-sequestral stages of necrosis. This, however, is a subject beyond the scope of the present paper. The other cases require no special comment.

Kashmir.

TWO CASES OF IDIOPATHIC INTRA-LARYNGEAL ABSCESS.



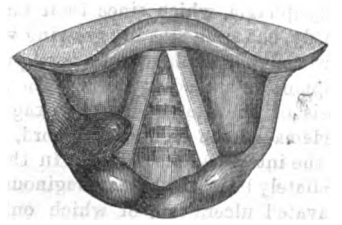
BY GREVILLE MACDONALD, M.D. LOND.

CASE I.—M. L——, a housemaid, single, aged forty, applied at the Throat Hospital on Aug. 27th, 1886, complaining of aphonia and odynphagia, which since their onset, eighteen months previously, had been steadily growing worse. There was a slight dry cough, complaints of a foreign body in the throat, and dyspnœa on ascending stairs. The laryngoscope revealed stenosis of the glottis, due to exaggerated congestion and œdema of the right vocal cord, chiefly subglottic, and of the inter-arytenoid fold. In this subglottic swelling, immediately beneath the cartilaginous glottis, was a spot of excavated ulceration, of which only the overhanging margin was visible. The left cord was congested and swollen, while the right was fixed in the cadaveric position. There was no marked change in the ventricular bands, but the aryteno-epiglottic fold of the right side was œdematous, and the arytenoid cartilage clubbed. The pharynx was anæmic, and presented three well-marked cicatrices on the posterior wall. There was no history of syphilis, although a sore throat of some weeks' duration was admitted as having occurred some fifteen years previously. The case was diagnosed as one of tertiary ulceration, upon which an attack of acute laryngitis had supervened. The localisation of the disease upon one side of the larynx pointed very strongly to some cause beyond simple catarrh. As the wards were closed for repairs, it was impossible to admit the patient. She was put upon ten-grain doses of iodide of potassium, and instructed to suck ice frequently and to inhale a weak alkaline spray every four hours. On Aug. 31st the patient's condition was much aggravated. Then respiration was stridulous, the supra-clavicular spaces receded during inspiration, and

Digitized by Google

the complexion was slightly dusky. The laryngoscopic appearances are represented in Fig. 1. The subglottic swelling had greatly increased, but receded sharply at the site of the ulceration; the margin of the right cord had almost disappeared, and the œdema of the aryteno-epiglottic fold was intensified. But the most striking alteration was the enormous swelling of the right ventricular band, which on examination with a probe appeared to fluctuate. In this swelling an incision was made on the most prominent point with Mackenzie's laryngeal lancet. Yellow creamy pus immediately welled up. The relief to the breathing was almost instantaneous, although the stenosis appeared unaltered. On Sept. 3rd the œdema of the right cord had entirely disappeared, although there remained some subglottic thickening. The iodide was continued under the supposition that the abscess might be a broken-down gumma,

FIG. 1.



and the patient was ordered to use a weak astringent spray. From this time the improvement was continuous, and on Nov. 30th the laryngoscopic appearances, beyond a slight hyperæmia of the cords, were normal.

Little comment is called for on the above facts. The trouble being of such long duration the etiology was somewhat obscure. The abscess may possibly have been due to an acute inflammatory attack supervening upon a chronic laryngitis; if so, the chronic symptoms were remarkable in disappearing so completely during the short time the patient was under treatment.

CASE 2.—F. W——, married, aged thirty-eight, applied for relief on Jan. 4th, 1887, complaining of odynphagia, more marked on swallowing saliva than with food, a symptom which generally points to the larynx rather than the pharynx as the seat of pain. She had taken cold a week previously, since when the pain had been steadily increasing. The pharynx was normal in appearance. The laryngoscopic image is represented in Fig. 2. The whole of the right side

FIG. 2.

of the larynx was considerably congested; while, projecting inwards from the right aryteno-epiglottic fold, and resting apparently on the ventricular band, was a smooth, dull red, somewhat translucent swelling, partly concealing the vocal cord. To the probe it appeared soft and fluctuating. With the laryngeal lancet pus was evacuated, and the prominence collapsed. The pain on swallowing was immediately relieved. A benzoic acid inhalation was prescribed. At the patient's next visit, a week subsequently, all traces of the inflammatory mischief had disappeared.

This second case is quite of minor interest save from its rarity. Idiopathic laryngeal abscess is scarcely discussed by authors. Morell Mackenzie has collected thirteen cases. Of these six occurred at the root of the epiglottis, four involved the ventricular bands, and three the aryteno-epiglottic folds. Nine were opened, the remainder undergoing spontaneous rupture.

Queen Anne-street.

THE EXPERIMENTAL PRODUCTION OF CHEST TYPES IN MAN.[1]

BY G. W. HAMBLETON, L.K.Q.C.P.I., M.A.I.

WHILST engaged in research on another subject, my attention was drawn to the fact that the size and shape of the chest varied as I varied the conditions to which it was subject. I found this sequence of events was absolutely constant, and could be carried out within such wide limits that it appeared to me to prevent an insuperable objection to the present accepted theory of the inheritance of chest types.

Taking a well-marked example of the so-called inherited consumptive chest, I subjected it to conditions that tend to develop the lungs, till it corresponded in size and shape first with the town artisan, then with that of a man of the privileged class, and finally with that of a man of the best class of insurable lives in America. By subjecting that same chest to conditions that tend to reduce the breathing capacity, I brought it back through the same types to nearly that with which I commenced, and I have produced similar results on other chests within a period measured by months. At birth the average male child of all classes has the same type of chest, but at maturity he has that of the class to which he belongs. Here, too, we have one type of chest forming a series of types that have varied precisely as the conditions to which they have been subjected in those classes have varied. Further, there is evidence pointing to the same relationship between conditions of type, in which none has ventured to raise the question of inheritance. We have, on the one hand, the type of chest of those who use wind instruments, or who by their occupation require to greatly use their lungs; and, on the other, the type of those who spend their time in a stooping posture, or who compress their chests either by the instrument they use in their work or by a corset. And there is the same relationship between the size and shape of other parts of the body, and the conditions to which they are subject. We know that the head has been altered in shape by direct pressure; that the muscular and osteal systems change in size and shape according to the conditions to which they are subject; that the colour and thickness of the skin vary in like manner; that the difference between the foot of a Chinese lady and that of a woman who has never worn shoes depends upon their presence and absence respectively; that the difference between the hands and fingers of a pianist and those of a man accustomed to lift heavy weights is produced by their occupations; and that each histological element of the body is subject to the same law. Therefore I contend that the type of man after birth is solely produced by the conditions to which he is subject. Hence the formation of race by man's continuance under the same conditions and its subsequent divisions into sub-races and families by his migrations into new conditions and the minor differences therein. Hence also the difference between the same species of animals under the conditions of nature and of domestication; the difference between the same plants placed under different conditions; the difference between the products of seeds sown in different localities, and the return of man, animal, or plant to former types on being subjected to the conditions that produced that type.

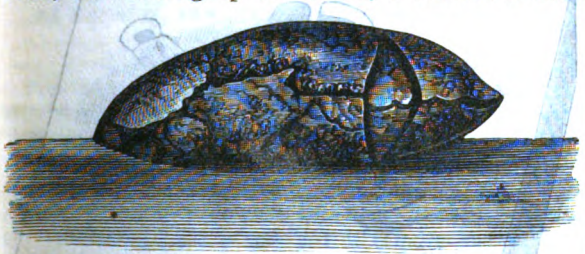
This opens up a wide and most important field for our investigation. We have to ascertain what the conditions are that produce these changes in each part of man that together form a class or type. The difficulties in our way are not nearly so great as will at first sight appear. Great demonstrations are constantly taking place before our eyes of the relationship between conditions and types in those trades and occupations that are carried on around us. Let us ascertain exactly what they can teach us by investigation, and then we shall be able to compare the results with those that will be obtained in other countries. Truly, it will be a work of years, but it will give us a science of man. When we have ascertained what the conditions are that produce these differences in each part of man that together make a class or type, we shall be able to produce that class or type. Further, this investigation will also tell us what type of

[1] A paper read at the recent meeting of the British Association for the Advancement of Science.

Digitized by Google

body is best suited for this or that trade or occupation, and for residence in this or that part of the world. Then we shall train men so that we shall no longer send them into occupations with types of body unfitted for the conditions of that occupation, and consequently we shall be spared the misery and loss of those numerous break-downs from unsuitability of type that are now daily brought before us.

Manchester.



Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

REMOVAL OF URETHRAL CALCULUS OF UNUSUAL SIZE.

BY WALTER HENRY BROWN,
ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY.

THE patient, a man aged thirty-six years, married, and the father of two children, came to me complaining of pain and difficulty in micturition. The condition had existed for ten years past, but had greatly increased during the last three years. He brought with him a sample of his urine, which was alkaline, offensive, and contained much pus and albumen. He had been following his employment of insurance agent up to the time of my seeing him. On examination I found a large hard swelling on the under surface of the penis, extending from the glans backwards for a distance of about three inches. He told me that the swelling had existed for some years (he could not say how many), and had gradually got larger. The meatus was closed by warty growths, and I failed to pass even a fine probe. He further informed me that he now passed urine drop by drop. Suspecting calculus, I sent him home, and later in the day had him put under ether, when, after slitting up the meatus, I removed a stone

Actual size.

weighing 265 grains, and measuring two inches and a quarter in length, and two inches and a half in circumference at its widest part. Mr. H. A. Smith, one of the house surgeons of the Infirmary, kindly made for me the accompanying sketch, which gives a good idea of the shape and size of the stone. The after history is unimportant, the man making a rapid recovery and the urine clearing within a few days of the operation.

The points of interest which occur to me are:—1. The unusual size of the stone and its position; the recorded cases of large urethral calculi mention them as having been either in the perineum or scrotum. 2. The fact of the man being able to endure the presence of this large calculus in the urethra, of its being apparently no hindrance to sexual intercourse, and, until very recently, not sufficiently painful to compel him to seek relief.

ON THE ESSENTIAL NATURE OF CERTAIN DISEASES OF THE SKIN.

BY T. FREDERICK PEARSE, M.D., M.R.C.P. LOND.

MANY will agree that too much attention is often bestowed upon the clinical symptoms and morbid anatomy of certain diseases of the skin, while the exciting or determining cause is left practically unconsidered. We notice, for example, eczema arising under a variety of conditions—such as that of rheumatism, gout, and external irritation. Nevertheless, we are apt to label the appearance "eczema" and consider we have got a distinct pathological process. In one sense, perhaps, we may be said to have a particular type of structural change in the eczematous group and another distinct change in the psoriasis group, but my contention is that just as the word "dropsy" only conveys a very general meaning of a patient's condition, so the terms "eczema" and 'psoriasis" similarly designate but groups of symptoms without definite pathological indications. We recognise a gouty bronchitis, and ought to treat it as for gout, and not as an inflammatory affection. When we recognise the gouty eczema, there is too much tendency to treat the local condition, and not to pay sufficient regard to the gouty state upon which the local changes depend. To take another example. At one time the joint affections of acute rheumatism, though admitted as part of a general state, were thought to require combating by local treatment. Now, however, we have found that the joints themselves require no local treatment whatever, and that we relieve them by overcoming the rheumatic process upon which these and other symptoms depend. Those who are engaged in the study of diseases of the skin will have come across cases of eczema which remain unrelieved, or at any rate uncured, by any local application, but which rapidly recover by the internal administration of the salicylates of hydrogen or soda. In these cases we may have a local state exactly similar to all intents and purposes to that arising from gout or other causes, but there is a distinct pathological process which we know as rheumatism underlying it. I am quite confident that there are other cases, again, termed "eczema" which are dependent upon influences from the nervous centres. We recognise that a very large number of cases of eczema are associated with some kind or other of intestinal disturbance. Many of these we treat successfully, but there are others in which we do not get at the *fons et origo mali*, and which remain an opprobrium to our art. Much the same may be said of other groups besides the eczematous. We know the cause of many diseases of the skin, but what I wish to lay stress upon is that though the terms "eczematous," "lichenous," "herpetic," "furuncular," &c., applied to groups of symptoms, may be useful for instruction, they are absolutely misleading if considered as distinct pathological processes, requiring a special line of treatment for each. Just as we call a particular form of joint affection an "arthritis" and a collection of serum in the tissues "dropsy," so ought we to apply the term "eczema" merely to certain clinical appearances of the skin.

I am quite aware that there is nothing new in the above remarks to sanction them for public print, but my object in bringing them forward is to advocate a classification and nomenclature based upon the etiology of diseases of the skin, rather than upon groups of symptoms or morbid anatomical changes. At some future date I hope to be able to suggest a classification founded on these lines.

A CASE OF FRACTURE OF SKULL; TREPHINING; RECOVERY.

BY A. J. POPERT, M.R.C.S.

ON the afternoon of June 3rd, a young farm labourer, whilst "skylarking" with other lads in a stable, fell, and was kicked on the head by a horse and rendered unconscious. He was dragged out of the reach of the animal's hoofs, but remained insensible for about ten minutes, when he slowly regained consciousness, and was carried into the neighbouring farmhouse. I saw him about two hours after the accident. His condition was then as follows. He was conscious, suffering apparently from shock; very pale; temperature 97·5°; pulse 48; and he was bleeding from a ragged wound in the scalp about the region of the middle of the anterior border of the right parietal bone; there was no paralysis. An examination of the wound by the finger discovered a sharp edge of broken bone about half an inch long, with depression of neighbouring bone. My brother, Mr. Alfred Popert, who saw the patient with me, and who all through the case rendered me much assistance, agreed that the trephine was indicated, not so much with a view of raising the depressed bone as to remove the loose fragments and splinters which the concentrated localised nature of the blow rendered probable. Accordingly the patient was anæsthetised, the scalp wound enlarged, and the injured

Digitized by Google

bone exposed. The depressed surface was less evident to the eye than to the finger, and, indeed, the whole extent of damaged external plate was comparatively trifling—a sixpenny piece would have covered it; but on raising the circular disc, loose fragments of the inner table were found in every direction round the wound. In all, twenty-three pieces were removed; some with extreme difficulty, for more than one piece was found too large for extraction through the trephine-hole, and had to be cut with bone forceps; and several sharp spiculæ had penetrated the dura mater and were sticking firmly in it. The scalp was sutured and the wound lightly dressed with dry lint. The patient, who bore the operation and somewhat prolonged administration of chloroform extremely well, was then carried home (about two miles) on an improvised stretcher, and put to bed in a dark room. His progress to recovery was uninterrupted, the treatment being low diet and quietude. In eleven days the scalp wound had almost entirely healed, with scarcely a trace of suppuration, and in fourteen days from the receipt of the injury the patient was up and convalescent; since then he has been an intelligent member of an ambulance class organised in his village. He wears a vulcanite plate as a protection over the scar; but the dense and strong cicatricial tissue which is rapidly forming will probably of itself soon afford all protection necessary for what the patient facetiously calls the "only soft spot in his head."

The interesting features in the case are (1) the very slight damage sustained by the external table of the skull when compared with the condition of the inner; the separated pieces of the latter weighed 130 gr., and covered a superficial area greater than that of a five-shilling piece; (2) the entire absence of symptoms of intra-cranial mischief, except the immediate insensibility due to concussion. The temperature never rose above 99°, though the dura mater was lacerated in several spots. The circumstances of the operation were somewhat unusual, the patient lying on a low and narrow settle fixed to the wall in a badly lighted farmhouse kitchen, and the only available nurse a gamekeeper. The case bears an interesting similarity in some particulars to one that came under my observation when house-surgeon at our local infirmary, and which I reported in THE LANCET at that time. In that case, which ended fatally, the blow was concentrated on one spot, having been administered by a lusty Irishwoman with the knobby end of a kitchen poker. There being no urgent brain symptoms, and not very distinct evidence of depression and comminution of bone, the expectant treatment was adopted, but the necropsy revealed abundant evidence of meningitis, cerebral abscess, and a depressed comminuted fracture with very sharp edges.

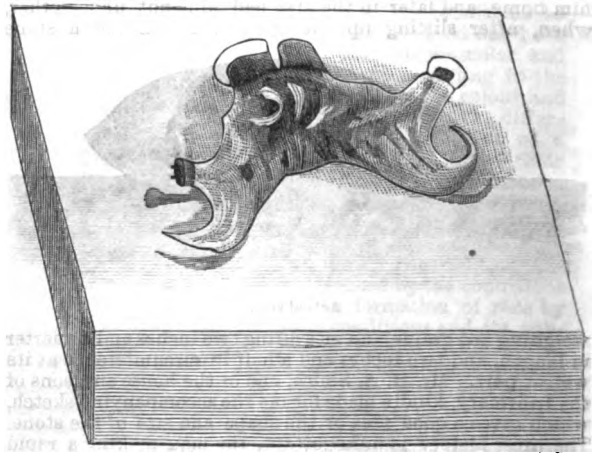
ANTISEPTIC MIDWIFERY.

By AMBROSE E. L. CHARPENTIER, M.B.

IT is with much pleasure I see the increasing interest taken in the above subject, and notably Dr. W. A. Duncan's most instructive paper on the "Accidents of Parturition." As one practising antiseptic midwifery, I beg to offer one or two suggestions, chiefly as to the means of carrying it out in ordinary practice.

Though not presuming to write "as one having authority," I would submit that there should be some additions in the "antiseptic" midwifery bag. It should contain as usual: forceps, catheter with tubing, syringe with uterine tube, pocket case, elastic or linen bandages for "auto-infusion" in case of collapse from hæmorrhage, hypodermic syringe, stylet, minim measure, and, advantageously for the safety of the patient and one's own comfort, a small nail-brush in metal case. There should be spaces for at least nine bottles; the six would contain, as in ordinary use, chloroform or the A.C.E. mixture, ergot, ammonia, ether, opium, and iron. In the others there should be—(1) A solution of chloral hydrate, twenty grains of chloral in a drachm of syrup of ginger or orange. (2) Bichloride tampons, carbolic acid, or a solution of bichloride of mercury, made by dissolving 160 grains of the salt in four ounces of spirits of wine; one drachm of the solution in a pint of water forms the 1 in 2000 lotion. I find this solution superior to the tampons; it is always easily prepared, is less bulky and less expensive. (3) An ointment of bichloride and vaseline (1 in 500), which is conveniently carried in a wide-mouthed bottle.

As regards the actual work, there is but little more trouble and a great deal more satisfaction than in the old happy-go-lucky method. In the syringing, a china tooth-brush tray, or soap-dish (almost always to be found), answers well to catch the escaping fluid when held close to the nates, the patient lying on her side in the usual position. This is easily done without any elaborate or expensive apparatus.



The universal practice of antiseptic midwifery cannot be too strongly insisted upon, and no trouble or anxiety on our part should be too great to prevent the horror of a case of septicæmia; and when we see by the mortality tables of puerperal women, as given in Kucher's excellent book on the Puerperal Diseases, that 10 to 18 per cent. of lying-in women die of puerperal diseases, and of these septicæmia claims 75 per cent., it is truly lamentable, and it should require no further incentive to urge us to make every effort to reduce such a terrible death-rate.

Uxbridge.

LODGMENT OF A TOOTH-PLATE IN THE GULLET FOR FIFTEEN MONTHS.

By HENRY E. BRIDGMAN, L.R.C.P.I.

AT 2 A.M. on April 17th, 1886, Thomas H——, aged twenty-eight, was brought to my surgery. He informed me that he had gone to bed, as was his habit, wearing a small plate, to which were attached four false teeth. He awoke, feeling the plate slipping into his throat, and he could, he said, still feel it at the top of his gullet. The patient was nervous and excited; he frequently retched, and expectorated blood-stained saliva; dyspnœa and dysphagia were marked. I examined the pharynx carefully with the finger, but failed to feel any foreign body. With a pair of throat forceps I seized something that I believed to be the plate, but on making an attempt to withdraw it, the dyspnœa increased, the patient struggled, and the forceps slipped. After several

fruitless attempts to seize the plate a second time, I desisted, and sent my patient to the Burton-on-Trent Infirmary. There probangs were passed into the stomach without meeting with any obstruction. The patient was watched for a few days, and then discharged, the dyspnœa and dysphagia having disappeared.

I saw the man a few weeks afterwards, when he was again suffering from dyspnœa, had a hard, frequent cough, and was expectorating copiously a tenacious mucus, tinged with blood. I continued to see him from time to time until Christmas, 1886. On July 25th, 1887, he presented himself again at my surgery, bringing with him the plate with false teeth attached, of which I enclose a sketch, saying that he had continued much in the same condition as when I had last seen him, being frequently unable to go to his work on account of cough and difficulty of breathing, until July 21st, when, being rather worse than usual, he felt, after a violent fit of retching, something in the back of his throat, when, by means of his thumb-nail, he hooked out the false teeth, which he brought with him and which he had lost just fifteen months since.

SEPARATION OF THE EPIPHYSIS OF THE SECOND METATARSAL BONE.

By JAMES MASON, L.R.C.P.ED.

THIS accident, though anatomically fairly likely to happen, as a matter of fact seldom takes place—at least I can find no written note concerning a case. On this account chiefly I think the following worthy of recording.

A girl, aged seventeen, came to me complaining of pain and swelling over the root of the second toe of the left foot. She stated that the "lump" had been there for some time; it occasionally disappeared when she put her foot in a certain position, but immediately she tried to walk it reappeared. I found on examination that it could be easily reduced, but it as readily returned to its old position when pressure was removed. The movement at the joint was perfect. Well-marked crepitus could be felt about a quarter of an inch behind the joint. The fragments were put in apposition and a pad applied. A strange feature is the patient having been able to walk about for so long a time. She could not remember having received any injury or twist, and considered it simply an "enlarged joint."

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

TWO CASES OF DISEASE OF THE THYROID: ONE TREATED BY EXCISION, THE OTHER BY INJECTION OF IODINE; RECOVERY; REMARKS.

(Under the care of Mr. HENRY MORRIS)

FOR the report of these cases we are indebted to Mr. Roger Williams, surgical registrar:—

CASE 1. *Hypertrophic goitre; thyroidectomy; recovery.*—The patient, a moderately nourished, fair-complexioned, and cachectic-looking girl, aged fourteen, from Dorking, was admitted on June 27th, 1884, with a large swelling in the thyroid region. She complained of being subject to very severe attacks of dyspnœa and of difficulty in swallowing. At night she was often disturbed by dyspnœal attacks. There were no signs of Graves' disease. Both tonsils were somewhat enlarged, and the lymphatic glands of the neck were normal. The swelling on the right side of the neck was the size of a very large orange, and reached from just below the hyoid bone to the sternum; that on the left side was not larger than a Tangerine orange. These lateral enlargements were connected by a swelling over the front of the trachea in the region of the thyroid isthmus. The mass moved with the windpipe during deglutition. It felt elastic, lobulated, and circumscribed, but there was no sense of fluctuation. At the upper part of each lateral swelling a large pulsating artery could be seen and felt. She gave the following history. Four years ago a swelling was first noticed in the site of the present disease, chiefly on the right side. It had since steadily increased, but more rapidly of late. During the last year she had been subject to severe dyspnœal attacks, especially during the night and after making any exertion. For some months she had suffered from increasing difficulty in deglutition. Her previous health had been good, with the exception of an attack of bronchitis four years ago. Her mother and sister, when young, both suffered from thyroid enlargement, which at length subsided. The sister's was frequently painted with iodine. Father, aged fifty, healthy. The family (five in number) are all healthy except the patient.

The symptoms becoming aggravated after the patient had been in the hospital a few weeks, it was decided to excise the thyroid. This was done on July 12th in the following manner: The patient being anæsthetised, an incision through the skin and fascia was made in the median line of the front of the neck, from the pomum Adami to within a little of the top of the sternum. The thin fascial investment of the gland was kept intact. The right superior thyroid vessels were exposed by reflecting the structures overlying them, and were ligatured with their sheath just as they entered the thyroid. The fascial investment was then cut through and the gland enucleated, the vessels at each of the other angles being seized by forci-pressure forceps and divided in the course of the enucleation, not before it. The vessels were of great size, and there was considerable venous hæmorrhage, quickly controlled, immediately after ligaturing the first set of vessels. Great care was taken not to drag upon the larynx and trachea, and there was no dyspnœa or suffocative effect throughout the operation. The growth proved to be a hypertrophic goitre. The wound was dressed with lint steeped in terebene oil and carbolic gauze.

The evening after the operation the temperature went up to 102·2° F.; on the following morning it was 100·8°; subsequently it remained nearly normal. The recovery was very rapid. She left the hospital convalescent six weeks after the operation, free from any impairment of voice, respiration, or deglutition. She was seen by Mr. Morris in January, 1885, quite well, and better than she had been for a long time previous to the operation. In June of this year (1887) Mr. Horace Chaldecott, of Dorking, reported that he had seen her frequently about the neighbourhood, that she looked and was quite well, and that she certainly had no symptoms whatever of myxœdema.

CASE 2. *Hypertrophic goitre; repeated injection of tincture of iodine; recovery.*—Jessie O——, aged seventeen, a short, dull and heavy-looking girl, was admitted on Sept. 10th, 1884, with a simple hypertrophy of the thyroid. She first had difficulty in swallowing, and noticed a swelling in the thyroid gland ten months ago. It had been growing very fast just previously to admission. No other member of her family has bronchocele, and she knows of only one other person in the neighbourhood in which she lives (Bovey Tracey, North Devon) with a similar swelling to her own.

On admission there was a large and regular swelling of the thyroid gland. Each lobe was equally enlarged, was solid, but semi-elastic to the touch. The swelling reached almost down to the sternum, and the circumference of the neck at the most prominent part of the swelling was fourteen inches. When she swallowed, the tumour rose with the larynx. She had some pain in swallowing, and had not taken any solid food for three months. Her speech was very low and indistinct. She had occasionally some dyspnœa, generally worse at night. There was a little albumen in her urine. She had menstruated regularly since fourteen years of age. The treatment adopted was the injection into a different part of the goitre of fifteen minims of tincture of iodine every other day, from Sept. 18th up to Oct. 17th; after this, twenty minims every third day till she left the hospital on January 14th, 1885.

On April 23rd, 1885, Mr. Goodwyn, of Bovey Tracey, South Devon, wrote in regard to the patient: "She now suffers from no pain or difficulty in swallowing. Her goitre is decidedly diminished in size, hard, and non-pulsatile. The right lobe is somewhat bigger than the left. The circumference of the neck at the level of the seventh cervical vertebra, and over the most prominent part of the goitre, is twelve inches and a half. She is not obviously anæmic, but she had hæmic bruits over the base of the heart, and suffers from breathlessness on exertion. She seems to have brightened up mentally from her stay in London."

Remarks by Mr. MORRIS.—These two cases, which happened to come under observation within a few months of one another, illustrate the very different treatment required for different instances of the same form of bronchocele. Both of them were cases of simple hypertrophy, which is the form of goitre least prone to give rise to serious symptoms, and most amenable to improvement from internal and topical remedies; which sometimes contracts and becomes transformed into a firm fibrous or calcified fulness; or which may spontaneously and completely subside down to the dimensions of the normal thyroid. In both these cases the disease had reached a stage at which it had been for some time seriously affecting the health of the patients, and that, too, at an age when simple hypertrophy is not generally wont to be more than a disfigurement at most. In spite of treatment by their respective medical attendants, these young girls had continued to grow worse—to suffer increasingly from dyspnœa,

Digitized by Google

dysphonia, and dysphagia; and one of them—she whose case is first recorded—had even her life threatened by the disease. Though the rate of growth in the second case was rapid, the fascial tissues of the neck had yielded sufficiently to prevent the occurrence of those very alarming symptoms which are commonly excited by acute hypertrophy of the gland. Indeed, though the change in the voice and the difficulty of swallowing solids were very marked, we had no immediate fear for the life of the girl, whilst the character of the tumour offered every inducement to try the injection treatment, which happily effected such a good result. That the improvement which followed the injection of iodine was really due to the treatment is proven, I think, by the rapidity with which the hardening and contraction of the gland followed the injections, and by the fact that these changes occurred exactly at the parts injected, and progressed therefrom. We thus cannot, I think, for these reasons, impute the result to any gradual and spontaneous transformation of the tumour from the simple or cystic to the fibrous form of the disease.

In the first case, the severe and frequent dyspnœa, not only on exertion but during rest and at night, the increasing difficulty in deglutition, the general feebleness of the patient, and, lastly, the aggravation of these symptoms during the three weeks she was under observation in the hospital, pointed to the necessity of early and efficient treatment, if her life was to be saved. The danger of these attacks of dyspnœa coming on suddenly, their fatality, and the disadvantages against which the surgeon has to contend when he has to operate on an emergency in the night, are well illustrated by Mr. Pitts in a record of three cases, in the Pathological Transactions, vol. xxxiii. p. 364. Moreover, the soft and elastic character of the swelling, together with the forcible pulsation of the feeding arteries and the evident large size of the vessels in the gland, seemed to exclude incisions, caustics, subcutaneous laceration, and the various injections; whilst our comparative ignorance of the value of electrolysis and galvano-puncture in this disease, the uncertainty and known dangers of setons, and the futility of the ligature of the thyroid arteries, left as the only alternatives excision of the isthmus and the removal of the whole thyroid. The latter was preferred as being absolutely certain in its immediate result, and because it was not contra-indicated by adhesions between the tumour and the great vessels of the neck, nor by extension of the growth downwards behind the sternum. The object in putting the case of thyroidectomy on record is because now, at the end of three years, the girl is in good health, and shows no sign whatever of any threatening of myxœdema, and because it adds another instance from which the committee of the Clinical Society, at present engaged on the subject, will draw their conclusions.

AYR COUNTY HOSPITAL.

HERNIOTOMY TWICE WITHIN THREE MONTHS.—NECROSIS OF RIB.—AMPUTATION OF ARM IN AN OLD MAN.—IMMENSE HYPERTROPHY OF HEART.

(Under the care of Dr. NAISMITH, F.R.C.S.E. (Exam.).

FOR the following notes we are indebted to Mr. F. G Clemow, M.B., C.M. Edin.

Strangulated umbilical hernia; two operations within three months.—Mrs. W——, aged forty-seven, housewife, an immensely stout woman, was admitted on May 26th, 1887. For fifteen years she had been the subject of an umbilical hernia. In February last it became strangulated, and was operated on in the Glasgow Royal Infirmary. After this it did not reappear till three days before admission, when it suddenly developed, and seems to have become rapidly strangulated, as vomiting and abdominal pain came on during the night. The vomiting continued at intervals, and was stercoraceous on the morning of admission. There was no motion of the bowels.

On admission there was a remarkable absence of pain, collapse, or anxiety. Temperature normal; pulse 93, and steady. Tongue soft, moist, and furred. In the position of the umbilicus was a tumour four inches and a half in its long—i.e., transverse—diameter, tense and elastic. The skin over it was red and thin, showing the V-shaped cicatrix of the former operation.

On the day after admission there was the same absence of urgent symptoms; but the hernia was still irreducible. Slight bilious vomiting, not fæcal.

On the following day, May 28th—i.e., the fifth day from the reappearance of the hernia,—stercoraceous vomiting with severe pain recommenced at 5 A.M., and at 11 A.M. Dr. Naismith operated. A single median incision was made, commencing on the abdomen above the tumour, and ending on the centre of the latter. The coverings were very thin. With some difficulty the constricting neck was divided at the upper part, with immediate relief of tension in the tumour. The sac was not opened. Owing to extensive adhesions the hernia could not be entirely reduced. Two hours later the bowels were moved, and again at 2.30 A.M. Vomiting ceased three hours after the operation.

Nourishment was given per rectum for two days, when digested food was retained by the stomach. The temperature never rose above 101·4°. The patient left the hospital on July 7th, having recovered without any interruption. A specially made belt, with cup-shaped shield, was procured for her.

Remarks by Dr. NAISMITH.—The history of this case shows that after the first operation in Glasgow the woman did not on recovery have recourse to the use of a truss or any supporting apparatus whatever. It is manifest that had the usual precaution been followed, a second operation would not, in all probability, have been rendered necessary. Before section, I need hardly add, the usual palliatives of opium, ice applications, and elevation of the lower half of the body received a fair trial.

Necrosis of rib; removal of a large sequestrum.—A. M——, aged twelve, for some years had had a sinus over the right fifth rib, with constant discharge; no cause could be assigned. A probe detected dead bone with an indistinct sensation of mobility. On May 19th, under chloroform, a small incision one inch long was made, and with dressing forceps a necrosed portion of rib five inches long was removed with slight manipulation. This sequestrum consisted of the inner surface of the rib, from which the outer surface had been more or less completely eroded. She remains in the hospital with a slowly healing sinus.

Remarks by Dr. NAISMITH.—This case was discharged cured, I believe, in the latter end of July, or more than two months subsequent to the operation. I would draw attention to the length of the necrosed portion of rib which was extracted.

Amputation of arm in a man of seventy-three.—T. N——, aged seventy-three years, was admitted on May 17th, 1887, with diseased elbow joint of five years' standing; the joint was quite disorganised with offensive discharge from two sinuses; there was considerable constitutional disturbance and great weakness, with evening rise of temperature. On May 20th the limb was removed through the middle of the upper arm by antero-posterior flaps; scarcely a drop of blood was lost. His recovery was remarkably rapid, the wound healing largely by first intention. The temperature returned to normal on the night of the operation, and only rose twice afterwards to 100°. He left the hospital on June 18th, with the wound almost healed, and his general health completely restored.

Immensely hypertrophied heart.—J. L——, aged twenty, was admitted with extreme symptoms and signs of mitral stenosis and incompetence, with great dilatation and hypertrophy. He died on July 5th. The heart was found to weigh twenty-four ounces and a half, the hypertrophy of the left ventricle being enormous. The mitral valve was excessively distorted and calcareous, extremely stenosed, and incompetent.

JULLUNDUR STATION HOSPITAL.

FATAL CASE OF EXTERNAL URETHROTOMY.

(Under the care of Surgeon-Major STEVENSON, M.S.)

J. F——, aged nineteen, a private in the Connaught Rangers, was admitted on Oct. 23rd, 1885, for stricture of the urethra. He had just arrived with a draft from England. The account he gave of himself was that six months previously he had fallen on a fender in his barrack room, striking his perineum on a sharp corner of the iron. Immediately after the accident he passed blood by the urethra. For this he was treated in hospital and had instruments passed. He was in hospital on board ship on the voyage out to India for stricture, but it is noted in his medical history sheet that no instrument could then be passed into the bladder.

On admission some attempts to pass an instrument through the stricture were made, but without success; and he was

Digitized by Google

treated by rest in bed and hot baths in the hope of introducing a catheter into the bladder later on; but all subsequent efforts in this direction failed. When first seen the stream of urine was small, but continuous; soon, however, the contraction of the stricture became so extreme that urine passed only by drops, and later still there was the constant dribble from an over-distended bladder. The urine was of high specific gravity (1030), clear, acid, and free from albumen. Under these circumstances operative interference was imperative, and the following procedure was carried out on Nov. 19th. An incision, one inch and a half long, was made in the middle line of the perineum on to the point of a No. 10 leaden bougie which was being pressed against the front of the stricture. The lower end of this incision was within half an inch of the anus. On opening the urethra a fine leaden bougie was passed (replacing the larger one), and its point bent up at an acute angle (no Wheelhouse's hook being at hand) so as to hook up the urethra at the upper end of the wound. The cut edges of the urethra being held aside, attempts were made to pass the point of a fine probe-pointed director through the stricture, but, although perseveringly persisted in, failed of success. Under these circumstances the performance of Cock's operation of opening the urethra behind the stricture became necessary. This was accordingly done, and a No. 10 silver catheter passed into the bladder from the meatus. The urethra behind the stricture was found to have become enormously dilated. The wound was dusted with iodoform and covered with carbolised oil on lint, with a padding of absorbent carbolised cotton wool outside. The operation occupied about an hour, and at it, and in the decision to perform it, Surgeon-Major Stevenson was assisted by Surgeon Pink, M.S., and Surgeon Dyson, F.R.C.S.

On the evening of the day of operation the man seemed to be doing well; the bladder was being freely drained; there was no pain. Temperature 100·2°. On the morning of the next day the temperature had gone up to 103·0°, but the man appeared to be doing well; he had no pain; the urine was being passed freely through the incision. The catheter was removed, and the wound, which was looking healthy, re-dressed in the same manner. He had taken opium pill (one grain) and had slept fairly well. On the evening of the second day he felt comfortable; drainage free; some urine had passed by the meatus; no pain or tympanites, but the temperature was 104·0°; bowels opened once. During the night, at about 12 o'clock, he became restless and uneasy, but he had no pain. Later on symptoms of collapse suddenly set in; he became cold, blue on the surface, and pulseless, and the temperature went down to 97·0°. At 7 A.M. on the third day these symptoms were most marked, and stimulants and the external application of heat had no restorative effect. The patient died at 9 A.M., about forty-six hours after the operation, evidently of acute septicæmia. He had passed urine freely during the night. The wound looked sloughy and grey in colour, but this unhealthy appearance had come on quite recently.

At the necropsy, six hours after death, the left lung was found to be adherent at the upper lobe from recent pleuritis, and œdematous and congested at the apex; right lung much congested and œdematous; recent red pleuritis at the front of the middle lobe. Spleen red and friable. There were effusions into all the serous cavities, and the stomach, intestines, pericardium, and pleuræ showed patches of congestion and ecchymosis. The bladder was small and contracted, and its walls enormously hypertrophied and hard; they were quite an inch in thickness; its mucous membrane was in folds, and showed many spots of ecchymosis. At the neck of the bladder, on the floor of the urethra, was a small false passage, a band of mucous membrane stretching across the urethra, as though a loose fold had been hitched up on the point of a catheter or sound and been pierced. The urethra behind the stricture was dilated to about the size of a man's thumb. The kidneys appeared healthy, and the ureters were not at all dilated.

Remarks by Mr. STEVENSON.—Why should this case have developed septicæmia? All antiseptic precautions possible in the treatment of a wound in the immediate neighbourhood of the anus were strictly adhered to; iodoform, carbolised oil, and absorbent carbolic wool were used as dressings; the instruments used at the operation had been kept in a 1 in 20 carbolic lotion for an hour or more previously, as were also the sponges; and the parts operated on had been thoroughly purified. Must the case be entered under the heading lately referred to in THE LANCET, and put down as a "surgical mishap"? Or may the catheter be to blame? The one passed into the bladder had been for some time in a 1 in 20 carbolic lotion, and it was lubricated with carbolic oil, but a catheter is an instrument of which it is difficult to guarantee the purity in a Listerian sense.

Reviews and Notices of Books.

Elements of Physiological Psychology. By GEORGE T. LADD, Professor of Philosophy in Yale University. Pp. 696. London: Longmans, Green, and Co. 1887.

THE prospects of psychology have of late years greatly brightened, for the advances of anatomy and physiology which are now carefully studied by psychologists, are at length beginning to bear fruit. No doubt much knowledge in regard to the laws of thought, the sequence of ideas, and intellectual phenomena generally, may be obtained by introspection, but so long as philosophers were contented, like the spider, to spin their theories from their own bodies instead of appealing to experiment and observation, no progress could be expected. Their reasonings resembled an inverted cone wanting its proper base to stand upon. The very title of the book before us, written by one of the ablest teachers in one of the best colleges in America, shows it is now understood that the study of the phenomena of the mind may and ought to be approached only by those who have obtained a competent grasp of the material substratum through and by which such phenomena are exhibited, and that a knowledge of the chemistry, the physics, the anatomy and physiology of nervous tissue, is a necessary preliminary to elementary conceptions of its mode of working. The number of workers on these subjects and the value of the memoirs published have greatly increased in the course of the last few years, and the mass of material which has accumulated will best be appreciated by anyone who will take the trouble to turn to the pages of, amongst many others, the volumes of Pflüger's "Archives" and the volumes of Hoppe-Seyler's "Physiologische Chemie."

It is not surprising, then, to find in Prof. Ladd's treatise the first two parts embracing 584 pages, out of a total of 688, devoted entirely to an account of the structure and functions of the nervous system, that might take a place in any modern work on physiology, the last part only being occupied with the Nature of Mind. A great defect is, however, still observable in the mode in which psychology is cultivated—namely, the entire omission of the consideration of the faculties of the lower animals, and the mode in which mental attributes undergo evolution. Nature must be long and curiously questioned in this direction before clear answers can be given to many psychological questions. How can we expect to explain the action of the complex apparatus of man and the higher mammals when we are still ignorant of that of the lower fish and the humbler reptiles?

The most interesting section of the volume before us is that which deals with the nature of mind. Dr. Ladd reasonably insists upon the unsatisfactory character of the statement sometimes made that the phenomena of consciousness are the product of the brain, if by this is meant that thought and intelligence bear the same relation to this organ that the bile does to the liver. No doubt molecular changes occur in every act of thought; but in order to "hold that mental phenomena are related to the substance of the brain in the same way as that in which the nerve commotions or molecular changes are related to this same substance, we must identify mental phenomena with molecular changes." But it is at present "impossible to identify the two classes of phenomena as phenomena"; and he goes on to show that even if it be admitted that different sensations

Digitized by Google

may hereafter be shown to be the result of the mode of motion of the waves of nervous excitation, yet that a collection of such sensations resulting from the excitations of the brain by no means constitute a real "thing." Each "thing" implies not simply a vast number of moving physical molecules on the kind and amount of whose motion the phenomena of conscious sensation are dependent, but a uniting energy and a unity in mind. 'Fifty million molecules, even when they are highly complex and unstable phosphorised compounds, gyrating in the most wonderful fashion with inconceivable rapidity, certainly do not constitute *one thing*. They do not by molecular constitution and activities even constitute a physical basis which is conceivable as a representation or correlate of one thing." It is not surprising to find that Professor Ladd holds strongly the opinion that the mind is a real entity, "a real being which can be acted upon by the brain, and which can act on the body through the brain." This, he thinks, is the only assumption that is compatible with all the facts of experience. The earlier chapter in which this difficult subject is handled is worthy of careful perusal.

In concluding this brief notice of Professor Ladd's work, we may observe that it affords evidence of wide reading, and that the facts he has gathered from many quarters are lucidly stated and brought very appropriately into relation with each other, and the whole treatise may be read with advantage by the side of Spencer's "Elements of Psychology." We may add that it is excellently printed, and when requisite for the illustration of the subject good woodcuts are introduced.

Notes on Anæsthetics; with an Appendix, Illustrative Cases, and Engravings of Anæsthetic Apparatus. By ARTHUR S. UNDERWOOD, M.R.C.S., L.D.S. First Edition. London: Claudius Ash and Sons.

Guide to the Administration of Anæsthetics. By HENRY DAVIS, M.R.C.S. London: H. K. Lewis.

CURIOUSLY enough both these little volumes claim Mr. Woodhouse Braine as foster-father. Mr. Underwood disclaims any special knowledge of the matters with which he deals, protecting himself against adverse criticism by the avowal that he has committed his proofs to Mr. Braine. However skilled and well versed in anæsthetics a man may be, it is of course impossible to compress into fifty-two small heavily leaded pages the wide subject of artificial anæsthesia; yet Mr. Davis has attempted to do this, while Mr. Underwood has given us seventy pages, with another forty pages of appendix. Sins of omission in both books are too plentiful for us to enumerate, and so we will dismiss them with an expression of regret that works professing to be guides to one of the most important and responsible duties which a medical man can be called upon to perform, should pass into circulation with so meagre and wholly inadequate an account of artificial anæsthesia, its promotion, dangers, and difficulties. Mr. Underwood in his preface says he has "no fear that the following pages will be found to lack the wisdom that is born of experience, or to contain matter that is in any sense unpractical." Whether readers of the book will be able to take so hopeful a view of the case we very much doubt. Throughout we notice an absence of method in arrangement, as well as an entire want of any practical rules such as might serve to explain to a novice how he should set about giving an anæsthetic. Besides this looseness of compilation (for Mr. Underwood naïvely tells us he has only adopted the work of other writers without having any pronounced views of his own), there is an absolute inaccuracy in many of his statements—such, for example, as that chloroform is at present the anæsthetic most frequently employed for prolonged operations. The best chapter is that dealing with nitrous oxide, a matter with which Mr. Underwood as a dentist is presumably most acquainted. Mr. Braine's paper, read before the Medical Society in 1884, is largely under contribution for the chapter on ether, while directions concerning chloroforming are mainly taken from Sir Joseph Lister's papers published respectively in 1861, 1870, and 1882. Paul Bert's experiments are detailed, but no mention is made of the now universally recognised fallacies underlying the whole of his research. The teaching in this chapter is, we think, most dangerous, and is out of accord with our present knowledge. Thus, Mr. Underwood says: "The general result of all these experiments" (Bert's and Payrand's—whose method, by the way, was anticipated in this country) "from the days of Snow down to now seems to point to the fact that there is *little or no danger of cardiac syncope* during the careful administration of chloroform" (the italics are ours); "still there are dangers, for many deaths have been recorded." These dangers are said to be fright, shock, and overdosing. And the chapter concludes: "Chloroform is not specially dangerous unless given in too strong a dose." Surely the special danger lies in the fact that it is so easy to give an overdose! Clover, perhaps the most expert administrator of this country, met with deaths even when employing his method, whereby only a vapour below 4·5 per cent. was inhaled; and yet Mr. Underwood asks us to believe that chloroform only "becomes dangerous if the ordinary precautions laid down are neglected."

Mr. Davis undertakes more than the author of the "Notes," making mention not only of the three common anæsthetics, but devoting thirty-six lines to methylene, ethydene dichloride, and anæsthetic mixtures, and nine pages to cocaine. We cannot agree in the opinion expressed in favour of Ormsby's inhaler, as that instrument transgresses every canon of successful ether-giving. Dr. Ormsby certainly never intended, as stated by Mr. Davis, to improve Clover's inhaler—indeed reference to his original paper shows this. Mr. Davis's preference for Ormsby's inhaler may explain his curious statement that "children are readily asphyxiated by ether." We hope many children have not suffered this terrible death; certainly no record has, in our knowledge, been made of such an untoward result of etherisation. Mr. Underwood gives us to believe that chloroform kills by arresting respiration through paralysis of the arytæno-epiglottidean folds; Mr. Davis ignores such a possibility, and informs us that chloroform kills by syncope, although he admits "the respiration serves as an excellent guide to the patient's condition." Spasm of the glottis is said to be sometimes caused in nervous persons by their voluntarily holding their breath; this is not usually accepted, and we should regard such a theory as untenable. Turning to the practical side of anæsthetics, we are surprised to find Mr. Davis advocating the administration of nitrous oxide gas two or three times in succession—a practice which we believe other anæsthetists regard as harmful and likely to cause headache and malaise. We regret that the author of this little manual has not given himself a fair chance of penning, concisely if he will, yet adequately, the essentials of anæsthetic administration.

ACCIDENTS IN THE ALPS.—It is stated by a Swiss newspaper that this year's death roll in the Swiss Alps is an unusually heavy one. In the short space of not quite a month 22 tourists met with accidents, of whom 18 were killed. The accident on the Jungfrau (canton of Bern) involved the loss of six lives; that on the Falkniss (Granbündten) three. One life was lost in each case in the accidents on the Morteratsch glacier (Granbündten), Molesa (Waadt), Gantrist (Bern), Leissigergrat (Bern), Säutis (Appenzell), Kaisereck (Freiburg), Dent de Corjan (Waadt), Schächenthal (Uri), and Diablerets (Wallis). There were no guides among the 18 killed, and only too many persons made ascents without guides. The four injured persons were all tourists.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1887.

THE success of the Ninth International Medical Congress is a matter for thankfulness. The interruption of the series of Congresses would have been little less than a calamity and a disgrace for the profession in all nations. Any serious imperfection in the meeting, either as respects numbers or the character of the discussions, would have been but little less unfortunate. But the Congress has been held under most honourable auspices; the famous hospitality of the United States has been fully realised; and those who went great distances to attend the Congress have been amply rewarded, and will return to their various countries and duties with higher impressions of their calling and deeper convictions of its progress, both on its scientific and its medical side. We cannot but rejoice that our own country was well represented in many of the Sections; the names of many well-known English physicians and surgeons will have been noticed in the reports which were received by cable from our special correspondents at Washington. We confess that we read the report of the concluding proceedings of the Congress with the most pleasurable emotions, and not least the remarks of the English members. A break-down of the Congress in Washington would have been only a less acute pain to us than a break-down in London. And we accept the concluding speeches of our countrymen and of our *confrères* of Berlin and Paris, Dr. MARTIN and Dr. LANDOLT, and others, as proof that the Congress has been worthy of its predecessors, that it contained a larger gathering of foreign members than any of them, and that it is calculated to promote the advancement of our art. Those in the United States who have worked to this end, in spite of much discouragement, well deserve the gratitude which was accorded to them by formal resolution. We have purposely abstained in our allusions to the Congress from pointedly referring to the domestic differences among our brethren in the States, which threatened to seriously mar the success of the Congress, if not to prevent it altogether. Those who persevered in spite of all opposition, and who have carried through the Congress so successfully, may well be satisfied. They have done a great service to their country and to their profession in all countries. It is not necessary for us to say that they committed no faults and made no mistakes. Such praise is not for mortals in a world so full of "spilt saltpetre" as ours. But they have carried through the Congress, and we thank them. There is yet one other service they can do: in any official action that now devolves upon them, to strive to obliterate the last relics of discord, and to hand on the light of truth and charity, undimmed and unqualified, to those in Berlin on whom will now rest the burden of responsibility for the next Congress. They can well afford to be magnanimous, and to help to make the representation of the States at Berlin so complete as to bear no traces of recent divisions.

The scientific value of the addresses and papers read at the recent Congress cannot be estimated till we have seen them in full. On the whole, judging from abstracts of the papers and discussions, we are inclined to say that they have been practical rather than theoretical, and have had reference to useful rather than transcendental aspects of medicine. Neither, so far, have we met with much indication of original matter in the papers. But this is no dispraise. It was meet that in the most practical nation in the world papers and discussions should take a practical turn, and deal with questions at their practical point. No branch of medicine can be said to have been neglected, from that which deals with the brain to that which deals with the risks of decayed teeth, including, by the way, several instructive cases of pyæmia. The statistics of vaccination were much advanced in a paper by Dr. JOSEF KÖRÖSI, Director of Communal Statistics of Buda-Pesth (to which we hope to make more special reference), and other questions of Public Medicine were made subjects of interesting discussion. Every branch of medicine was well represented—notably the ophthalmic, the gynæcological, and the dermatological; so that we venture to forecast that the volumes of the Transaction Reports will have considerable practical importance.

THE Metropolitan Asylums Board, after sacrificing a week of valuable time, last Saturday reversed the unfortunate vote at which they arrived seven days previously, and they have now decided to open the Winchmore-hill hospital for the reception of the ever-increasing number of scarlet fever patients. By turning such places as laundries and linen stores into wards, and by decreasing the amount of cubic and floor space to which each patient is properly entitled, they have so far been able to receive all the sick sent to them, and we can only express a hope that the preparations at Winchmore-hill may be so rapidly pressed on that no block may occur in the working of the system which London has endeavoured to mature for the isolation of the infectious sick. Scarlet fever is still steadily on the increase in the metropolis, and there is no reason for believing that it will materially diminish until we are well into November, or even until the close of the year. The delay which the mischievous vote of Saturday the 10th inst. has brought about can only do harm, and already we learn that owing to it the usual tenders in connexion with the work of furnishing will have to be dispensed with; and thus the very attempt at economy, which was regarded as a foremost consideration by some of the opponents of reason, will in all probability now result in a necessary extravagance.

But even if all succeeds in connexion with the present epidemic, it will be a long time before London forgets the exhibition of unfitness for their posts which a large number of the members of the Asylums Board have exhibited. One of the greatest evils attending the sanitary administration of the metropolis has been the subdivision of authority; but, in a few respects, London had flattered itself that needless division had been got rid of, and the Metropolitan Asylums Board was looked upon as a body on which the metropolis as a whole was represented. Now we learn that it is possible for a majority of that Board to ignore the needs of the community on the occasion of an emergency such as Londoners are passing through, and so air their ideas

Digitized by Google

of economy, as well as show their want of appreciation of the most elementary portions of the duties assigned to them. As we said last week, it is the Poor-law element that needs largely to be eliminated from a body which, whether those they isolate are in receipt of relief or not, has to perform some of the most important sanitary functions that could possibly be delegated to them. They have, it is true, in this instance cried *peccavi*, but the chairman having received a letter from the President of the Local Government Board which in official terms told him that the Asylums Board had failed in their duty, and expressed the opinion that that duty ought to be performed without further delay, makes a public statement to the effect that the central authority ought to have told them what their duty was at an earlier date. What this means it is difficult to say; but that it was a statement deliberately made is the more evident because it was also embodied in a written communication addressed to the President of the Local Government Board. The public will naturally ask what the Asylums Board is for, if, with a staff supplying their officers daily with evidence that their hospitals are filling to overflowing and that the demand for accommodation is still on the increase, they need to be told in advance by the central authority what their action should be under such circumstances. One reason alleged for the intervention of the Local Government Board is that it had medical advisers whose counsel was available at so important a juncture. This may be, but it is certain that the Asylums Board should have all the information as to their own institutions and work which the central authority are able to obtain, and it is evident that there is a complete misunderstanding between the two bodies as to which of them should be prepared to provide matured medical advice in respect of the general work of the isolation of infectious diseases in London. That such advice has all along been and is still lacking must be obvious to anyone who has followed the history of the Asylums Board in its dealings with small-pox. Now the Chairman tells us that his Board looks elsewhere than to its own resources in order to learn how to deal with an epidemic of scarlet fever, and his colleagues receive the statement with signs of approbation. The outlook is by no means promising.

THE Address on Fever delivered by Professor AUSTIN FLINT before the International Medical Congress comes opportunely at a time when attention is being more than ever attracted to this subject. There is, moreover, a wide contrast in the manner in which Dr. FLINT has dealt with the question and the line of argument adopted by Dr. MACALISTER in his recent Gulstonian Lectures. For, although basing his reasonings upon physiological grounds and facts upon which as a physiologist he has every title to be heard, there is hardly a single note throughout his address upon the aspect of pyrexia with which Dr. MACALISTER so fully and so ably dwelt. The reason for this silence upon the intricate subject of the relation of the nervous system to the production of normal and abnormal heat is perhaps not far to seek. Professor FLINT would be the last to ignore the importance of this aspect of the question, but he seems to have chosen to drive home certain practical lessons, rather than to venture upon the boundless field of theoretical speculation. In so deciding he has rendered no mean service, and has ensured to his address a wide attention on the part of the profession. He has nevertheless found it necessary for the continuity of his argument to make one assumption, which modern discovery goes far to justify. The essential fevers, he affirms to be due to a special cause—a micro-organism,—the operation of which ceases after the lapse of a certain time. This assumption has almost gone beyond the stage of a reasonable hypothesis; for not only have specific pathogenic microbes been detected in the blood and tissues of a great number of fever patients, but the known facts of contagion, of incubation, of the self-limited duration, and the immunity conferred by one attack against a second, which characterise so large a proportion of this class of diseases, are strictly in conformity with all that is as yet known of the properties and vital conditions of microbes. What, then, can be simpler than to assign the leading phenomena of the febrile state to the operation of the vital activities of these minute parasites? But when it is granted that these are the morbific agencies, we are still a long way from solving the next problem—namely, the mode in which they operate; and Professor FLINT did not venture to supply this link in the causation of the febrile process. Whether the poison they generate acts upon the heat-controlling centres in the nervous system, whether the presence of the microbes in the blood is more directly a cause of the tissue changes which are at the root of the increased production of heat, or whether they operate in some manner as yet unconsidered by the theorist, it is certain that we have not the knowledge requisite to supply this hiatus. Much has been done, notably by Dr. BURDON SANDERSON, and we have derived therefrom some facts as to the chemical changes which are in operation; but for all that, at the present time we must be content to accept the bare fact that fever, which is characterised by an excessive production of heat, is concomitantly marked by excessive tissue metabolism, with resulting inanition.

This practically was the position assumed by Prof. FLINT, and we owe much to him for so clearly bringing into relief the physiological phenomena which characterise the maintenance of animal heat and the pathological features of the febrile state. In doing so he introduced a novel, and at the same time a most important, point for consideration. From his own and other observations he clearly proved that in the normal process of nutrition, whereby the heat of the body is maintained, the formation of water is an essential factor. This is a point which has certainly been lost sight of. Attention has been concentrated upon the excretion of carbonic acid and urea as indicative of the oxidation of food and tissues; but the facts that the water daily excreted is in excess of that ingested, and that a large proportion of the hydrogen of the ingesta is by no means represented in the egesta, justify the conclusion of Professor FLINT that the oxidation of hydrogen is an important element in nutrition, and that, as regards the animal economy, water is to be placed in the same category as carbonic acid and urea. In muscular work, which is accompanied by increased heat and increased elimination of carbonic acid and urea, there is also increase in the discharge of water. But in fever the normal metabolism is

Digitized by Google

deranged. There is excessive oxidation of tissue, which the food supply is insufficient to counterbalance, and consequently there is an increased excretion of carbonic acid and urea. The fatty tissue is consumed; the muscular tissue and gland cells degenerate; but with all this evidence of increased oxidation there is a diminished formation and suppression of discharge of water. This last-named circumstance is held to account for a great part of the phenomena of fever. For although in health the oxidation of hydrogen takes its share in the production of animal heat, yet the water thus produced is available for the equalisation of temperature by cutaneous transpiration. In fever the suppression of this product of oxidation is wanting. The pyrexia, says Professor FLINT, "is fed, so to speak, by the fatty and solid tissues of the body alone." The disturbance in the economy due to the lack of water heightens the fever, owing to the consequent suppression of the cutaneous functions, and increases the disintegrative processes. For "in simple inanition the tissues of the body are economised by the excessive formation of water and the increased prominence of this process in calorification."

The application of these facts to the rational treatment of fever was made by Professor FLINT in a manner which proved the harmony subsisting between physiological inquiry and practical medicine. He showed that in the treatment of fever the abstraction of heat by external cold is one of the most rational of procedures; for in fever we have as a fixed condition an increase of the process of calorification. By the application of cold to the surface we abstract the excess of heat, and thereby reduce the temperature of the body. The proof of its efficacy lies in the notable subsidence of the nervous derangements which are secondarily due to the heightened temperature. The administration of antipyretic drugs has a similar effect, but the explanation of their action is obscure. It is possible that they operate by restraining metabolism, but, after all, our use of them is largely empirical. One of the chief lines of treatment of fever is that indicated by GRAVES—suitable and sufficient alimentation. Hampered as we are in this respect by the enfeebled digestive powers, Professor FLINT thinks we may do more than we are in the habit of doing in the way of administering fatty and farinaceous foods, the great object of alimentation being to retard and repair the waste and degeneration of tissue, and also indirectly to save the tissues by furnishing material for oxidation. On this ground he argued strongly for the retention of alcohol in the fever diet, maintaining that its ready oxidation rendered it a most suitable food, whilst it at the same time supplied the water of which the body is so much in need. In this connexion he alluded to the probable normal production of alcohol in the body from sugar; and he further illustrated the point by a reference to diabetes, where, in spite of increased consumption of nitrogenous and fatty substances, there is wasting and a diminished temperature, because the sugar is perverted from its normal office in the economy and is discharged unchanged. Professor FLINT admits, and no one can gainsay it, that the administration of alcohol in fever has been abused; but he has, none the less, done good service in once more recalling us to the sense of its value, when judiciously given as a hydrocarbon which can be utilised without any undue strain on the digestive or assimilative powers.

A LETTER from Mr. ED. W. WILMOT, which appears in a contemporary under the above heading, first expresses the opinion that true cholera does not exist in Malta, and then gives certain information having important bearings on the question of quarantine. We do not propose here to discuss the correct name of a choleraic disease which, according to published returns, killed 177 persons out of less than 300 recorded attacks up to the middle of this month, but we would point out that, if these returns even approach trustworthiness, there is not much to choose between "this choleraic diarrhœa" of Malta and the true Asiatic disease. But the writer's other statements deserve more than a passing notice. He refers to the grave distress and poverty which prevail, and points out how the disease is limited to the Maltese labouring classes as opposed to the troops. The former class are suffering severely, and poverty with its depressing influences, together with insufficient and bad feeding, are but too well known to act as predisposing causes to the spread of cholera; the latter class are well fed, properly housed and cared for, and so far they have immunity. But why has so great a contrast arisen between the two classes? The letter supplies the answer. The real distress is due to want of work, caused by empty harbours and deserted quays. And why has business so largely come to a standstill? Because the various nations have, with but few exceptions, put Malta in quarantine. Now Malta has always taken a very prominent position as regards quarantine measures, enforcing them with severity against other countries suspected of having cholera. Her attachment to those measures has not prevented her from being attacked with cholera; and now she is learning the lesson that, apart from their failures, those measures induce the very conditions which tend to the spread of the disease against which they are aimed. Her apologist also pleads for the removal of the barrier which others have seen fit to set up around her, and urges that there is no reason for it. The examples of Italy and of France are quoted, and it is stated that "no quarantine is imposed on passengers from Malta either at Marseilles, Naples, or on the Franco-Italian Railway frontier." But the truth is that Italy, and in some degree France, are progressive nations on this subject. They have had bitter experiences of the utter uselessness of quarantine restrictions; and Italy, having first abandoned land quarantine, has this year abandoned quarantine by sea; whereas France has given up her trust in quarantine by land, and would now not even impose sea quarantine against Malta. The lesson is, we trust, being learned, though slowly, that it is to the adoption of sanitary measures, and not to the imposition of quarantine restrictions, that Europe must trust for the prevention of cholera; and it is to be hoped that next time a rumour of cholera appears in the Mediterranean, Malta will imitate the example which is now being set to her at Marseilles and at Naples, and that, instead of issuing placards warning people away from her ports, she will so organise her sanitary arrangements that any imported infection can be properly dealt with without its finding on shore the conditions favourable to its development and spread.

Digitized by Google

Malta has all along been a great barrier in the eyes of Europe generally to the abandonment of useless and vexatious quarantine restrictions, for those who would induce other nations to follow the English lines of cholera prevention have often been reminded of the proceedings taken by this little English Mediterranean colony. We believe that, in so far as these antiquated measures are concerned, the colony is self-governing, and hence we must await the time when those responsible for her internal government shall have learned, by such experiences as her population is now going through, whether to trust as heretofore to the old-fashioned restrictions or to adopt true measures of sanitary prevention.

Annotations.

"Ne quid nimis."

LONG SITTINGS OF THE COMMONS.

IT is, we believe, understood that some endeavour will be made at the commencement of the next session of Parliament to procure such additions to the Standing Orders as shall be effectual for the prevention of that wanton and ruinous waste of time and strength which has in recent years taken the form of prolonged sittings, as a piece of tactics used by the Opposition in the House of Commons. The postponement of the adjournment is no doubt not only an obstructive, but a very destructive policy. The Closure is scarcely of a nature to admit of its extensive use. If this summary ending of a debate were adequately employed, it would be held to be abused, and speedily fall into discredit, with the result of its abandonment by successive Parliaments. What is wanted is probably a fixed limit to the sittings of the House, something like the rule that obtains on Wednesdays, but without the penalty of dropping Orders. It would be absurd to provide the Opposition with a power of talking out measures wholesale. To outsiders it would seem that one of two methods might be adopted—either to order that the House should stand adjourned every day at 1 or 2 o'clock A.M., or to make the Closure an automatic rule coming into force at a definite period of each debate, unless the Opposition could show the strength now required to enforce the closure. Perhaps this last suggested procedure would be the simplest, as it would cast on the party of delay the onus of showing a numerical strength sufficient to entitle it to prolong a discussion beyond reasonable limits. It has been suggested that the time to be occupied by speeches should be limited, but there are difficulties in the way of any such plan as this which it would be extremely difficult to overcome. From the health point of view—that from which we, of course, mainly regard the question,—it is imperative that effective measures should be devised. Very grave mischief is being done to members of all parties by the prodigal waste of strength caused by long sittings. Not only are Ministers, who must needs work at their offices or in departmental business nearly all day notwithstanding the fact that they are kept up at night, exhausted, but the strain is very great on all members of the House of Commons, and especially on the professional men and merchants who now constitute a considerable proportion of the Lower House of Parliament. The effects of these long sittings are beginning to show themselves in the impaired health of members generally, and the time cannot be far distant when a heavy mortality will begin to be apparent, the inevitable penalty of an abuse of physical as well as mental powers which nature will not tolerate. The atmosphere of the House is bad, and each session it is becoming worse. If the present system of reckless strain on the vital strength of our law-makers is not quickly reformed there will be a catastrophe, which too late must recall the House to reason.

TREATMENT OF CASES OF BITES BY RABID ANIMALS.

THE report, drawn up by Mr. V. Richards of Goalundo, and forwarded to the Inspector-General of Civil Hospitals, Bengal, concerning cases of animal bite treated by potassic permanganate at the various dispensaries in Bengal contains matter of an interesting nature, but of little practical value. We are glad that the tone in which the report is written does not partake of any bitterness against the Pasteurian method of treatment of animal or rather rabid bites, and we feel also that the conclusion at which both its author and the Inspector-General arrived, to the effect that the method of treatment should have a further trial, will commend itself to the heads of the Municipal Government of Bengal. M. Pasteur is said to have treated 48 individuals supposed to have been bitten by rabid wolves, and of this number about 14 per cent. are said to have died, and it is curious that the mortality percentage of cases in which the bite was inflicted by rabid jackals treated by the potassic permanganate method, as gathered from Mr. Richards' returns, was practically the same. There is nothing novel in the permanganate method of treating wounds inflicted by rabid animals; and seeing the object of the treatment is to destroy the virus *in situ*, it may well be doubted whether, after the lapse of some little time, it would be possible, in the case of the rabies poison, to completely destroy even the virus which remained about the wound; and although the poison is considered to remain at the site of introduction, it is questionable whether this view is strictly correct.

IRISH VITAL STATISTICS FOR 1886.

WITH commendable promptitude the Registrar-General for Ireland has just issued his twenty-third annual report, dealing with the vital statistics of Ireland for last year. The corresponding report for England and Wales will certainly not be in the hands of the public much before the close of the year; and it is scarcely three months since the Registrar-General for Scotland issued his annual report for 1884! Due credit is therefore due to the Registrar-General for Ireland for having found the means to issue his annual report within eight months of the close of the year to which it relates. We must confess, however, to some disappointment at the contents of the report proper, which occupies twenty-nine pages; of these, fifteen are devoted to meteorology, and but eleven to the discussion of the vital statistics of the year. The abnormal condition and age distribution of the Irish population invest the vital statistics of that country with exceptional interest, and it is disappointing to find that the report just issued affords no ready means for judging of the effects of these disturbing influences upon the vital statistics of the country. For instance, we are told that the birth-rate in Ireland in 1886 was equal to 23·3 per 1000 of the estimated population, and that it was 1·4 below the mean rate that prevailed in the ten preceding years. It should be remembered, however, that the birth-rate in England and Wales in 1886 was 32·4 per 1000, or 9·1 higher than the rate in Ireland; and it would not be without interest to have some light thrown upon this wide variation between the birth-rates of the two countries. It appears that the estimated population of Ireland in the middle of 1886 was 388,046 less than it was in the middle of 1876, and it is obvious that this decrease, caused chiefly by emigration, consisting mainly of young adults, must seriously affect the reproductive capacity of the Irish people. In order to correct for this elimination of young

Digitized by Google

adults from the Irish population, let us calculate the English and Irish birth-rate in 1886 upon the estimated number of women aged from fifteen to forty-five years in each country. Calculated in this way, the births registered in England in 1886 were equal to 141 per 1000 women of these ages, while the proportion in Ireland was 104 per 1000. Even these corrected figures must, however, still understate the true fecundity of the Irish population: (1) because it has been assumed that the *proportion* of women aged from fifteen to forty-five years in Ireland in 1886 was the same as in 1881, notwithstanding the continued large annual proportion of emigration; (2) because the proportion of married women at these ages is probably larger in England than in Ireland; (3) because the proportion of illegitimate births is much larger in England than in Ireland; and (4) because it is probable that in Ireland a far larger proportion of births still escape registration than is the case in England. These are some of the reasons which detract from the value of the mere birth-rate to population in Ireland for the purposes of comparison with the birth-rates in other parts of the United Kingdom, where the age distribution of the population is so different. Similar difficulties stand in the way of accepting the gross death-rate in Ireland as an entirely trustworthy measure, for comparative purposes, of the true mortality of the population of Ireland.

WORKING-CLASS BIRTH-RATES.

THE social and political importance of the birth-rate among the working classes, and its effect upon all population and vital statistics, invests with undoubted value all trustworthy information on the subject. The recently issued report of the medical officer of health upon the sanitary condition of St. Giles's in 1886 contains some information bearing, among other things, upon the varying birth-rate in different parts of this sanitary district, which has deservedly given rise to some comment. The district of St. Giles includes, besides the parish of St. Giles-in-the-fields, the parish of St. George, Bloomsbury, and is divided into three registration sub-districts—St. George, Bloomsbury, St. Giles South, and St. Giles North. The report in question states the birth-rate in these three sub-districts to be 21·9, 43·5, and 19·7 per 1000 respectively. These wide variations are thus explained by the medical officer. In Bloomsbury the low birth-rate is due to the large proportion of domestic servants included in the population housed in the squares and broad residential streets around the British Museum. In St. Giles North the low rate is, not so conclusively, attributed to loss of population through clearances for new streets—meaning, we presume, that the population of the sub-district is over-estimated. With regard to the high rate, 43·5, in St. Giles South, it is said to be due to the number of children born in the Peabody Buildings and the British Lying-in Hospital. As this part of the sub-district also shows an abnormally high death-rate, these facts have suggested the question whether it is a "necessary condition of human life that the weakest and worst members of the species should reproduce themselves most rapidly"? Now it is not a fact that what are known as "slums" have generally high birth-rates, although nearly all blocks of *improved* dwellings for the working classes show abnormally high birth-rates. If the birth figures for St. Giles South are looked at a little more closely they will be found to be misleading. If due correction (for which the report gives the necessary figures) be made for the births in the Peabody Buildings in Wild-street, and in the Lying-in Hospital, the birth-rate in the rest of St. Giles South is reduced from 43·5 to 31·7, which is 0·5 below the average for the whole of London. It is stated in this report that the birth-rate in the two blocks of Peabody Buildings situated in Great Wild-street and in Little Coram-street was 43·8 and 53·6 per 1000 respectively in 1886, and the last annual report issued by the trustees of the Peabody Donation Fund shows that the birth-rate among the rather more than twenty thousand persons housed in these improved dwellings last year averaged 42·4 per 1000, or more than 10 per 1000 above the general London rate. It should, however, be borne in mind that these, as well as most other, blocks of improved industrial dwellings are almost exclusively inhabited by married couples, in the prime of life, belonging to the better paid of the artisan class, among whom the birth-rate is bound to be high. Most of the unmarried young women of this class are in domestic service, large numbers of the single men live in common lodging-houses, and most of those past work or out of work are either packed away in the "slums" or are in workhouses. It is therefore most misleading to accept the birth-rates in improved dwellings as the birth-rates of the working classes. The working classes, compared with the upper and professional classes, undoubtedly marry young, and therefore would probably yield a higher birth-rate; but there is reason to doubt whether the birth-rate of the whole weekly-wage-earning class is much higher than that of the shop-keeping and lower middle class. It is much to be regretted, however, that no thoroughly satisfactory statistics on this subject exist, as it is one on which doubtful conclusions are frequently drawn from very insufficient data.

MEDICAL CERTIFICATES.

THE giving of a medical certificate, though one of the simplest of the duties that fall to the lot of the medical practitioner, is also often one of the most thankless. An illustration of this has just been brought to our notice. Mr. J. G. Fitch, who is one of Her Majesty's chief inspectors of education specially detailed to the examination of training colleges for female teachers, declares: "It is the complaint of the medical officers of the colleges that this testimony is often very untrustworthy [i.e., testimony to the health of candidates for admission to the training colleges] and that they are compelled to protect themselves by much further examination, even when the certificates given by local medical practitioners have been of the most positive and unqualified kind." We have no means whatever of knowing what foundation of fact there is for this complaint. However that may be, the accusation is not of such a kind as ought to be made in general terms. But it is more than likely that, having once been made, this remark will be repeated from time to time. It is well, therefore, that the attention of our readers all over the country should be drawn to it, and that some hint should be afforded to them of the construction the Training College authorities incline to put upon a candidate's certificate of health. Upon this point Mr. Fitch writes: "Since by the conditions of arts. 130-132 the grants paid to training colleges are in a large measure determined by the number of young persons who successfully complete their two years' training, and who afterwards serve for a satisfactory period of probation and obtain their certificate, it becomes the interest of the authorities of those institutions to receive only those students who are likely to complete their course with credit. The most careful inquiries are made, therefore, respecting their character, previous career, and social surroundings; and, considering that the young people are about to enter a laborious profession, special testimony is required respecting their health." We think that a guess may be hazarded here as to the real cause of the misunderstanding which the Chief Inspector reveals. It is easy to understand that the practitioner to whom a girl applies for a certificate of health preparatory to admission to a training college has questions of infection and freedom from incapacitating

Digitized by Google

maladies in his eye rather than the pecuniary interests of the colleges, and that nothing on such an occasion is further from his thoughts than to examine as if he were passing a lad into the army or a candidate for an assurance company. And we are bound to add that it is his duty to hold an even balance between the colleges and the candidates, and carefully to shut out from his view considerations of the sort upon which the training colleges would seem to insist. It would be monstrous if a capable woman, or man either, could be debarred from choosing the profession of a teacher merely because somebody else promises to earn a training school a larger grant.

SCLEROSIS OF THE HEART.

ACCORDING to Huchard the causes of sclerosis of the arteries of the heart may be divided into three groups: the first being due to intoxications, or rather toxæmia, by alcohol, tobacco, malaria, and lead; the second group is formed of causes such as the diathetic states of arthritism, gout, and syphilis; whilst the last group, and one to which exception may with at least some reason be taken, is composed of causes such as physical, moral, and intellectual over-pressure. The sclerosed heart may be either hypertrophied or dilated, but most often dilatation and hypertrophy are associated. Modifications of the form and size of the heart are the direct consequences of the initial vascular lesion, and not of the ensuing sclerosis. The common lesion is obliterating arteritis of the small coronary vessels, and it takes place slowly, so as to allow of time for compensating hypertrophy and for sclerotic lesions to develop. If the arteritis is of more rapid progress, dilatation of the heart and alterations of the heart-muscle fibres are the preponderant changes. Three histological varieties of cardiac sclerosis may be differentiated, following Weber: (1) perivascular sclerosis due to the propagation of inflammation; (2) the dystrophic sclerosis from regional ischæmia; and (3) mixed sclerosis. The changes in the muscle fibres are but imperfectly known. Two of the principal alterations are simple atrophy and the vitreous degeneration of Zenker. Nosographically, cardiac sclerosis is one of the anatomical expressions of arterio-sclerosis of the heart. Weber regards arterio-sclerosis as the outcome of certain etiological conditions, amongst which must be ranged heredity, certain hygienic habits, and various chronic intoxications.

MEDICAL EXAMINATION OF MISSIONARIES.

AT no time is the need of due medical examination and sanitary supervision more urgently needed than when troops, especially young troops, are being sent abroad to some tropical climate where ague, dysentery, and other serious diseases are endemic. Missionary societies, which are constantly sending out young men and women, who have frequently passed a large part of their lives in study or in sedentary occupation, to more or less unhealthy climates, are not, as a rule, as careful as they should be with regard to weeding out unsuitable constitutions by strict and careful medical examination, nor do they generally supply the young missionary with medical or sanitary regulations to guide him in his work. He is, it is true, usually sent to an older missionary, from whom he receives many valuable hints; and if there should happen to be, as is only too rarely the case, a brother medical missionary in the station, he ought to be at no loss for guidance. Nevertheless, it not unfrequently happens that a young missionary is left alone in an isolated and unhealthy place, and if his zeal (which is usually considerable) is not tempered by discretion the consequences to his health may be serious. A young missionary has lately succumbed to an attack of fever (due at first to a wetting) on the West coast of Africa, and a good deal of discussion has been taking place in the organs of the religious denomination with which he was connected with regard to the question of whether anyone was to blame. It is thought by some that his general condition was such as ought to have precluded his being allowed to go to such a climate. Whether he was or was not medically examined before being sent out, his death may well serve as a caution to those who have the duty—honorary, it may be, but perhaps all the more responsible on that account—of deciding as to the fitness of missionary candidates for tropical climates, to weigh the circumstances very carefully, and to keep their minds entirely free from the bias natural to those who take an interest in missions, but which ought not to be allowed for a moment to interfere with the opinion dictated by purely scientific considerations. The truer and more scientific the opinion given, the less will the missionary work suffer.

THE EXETER CATASTROPHE.

THE jury empanelled to inquire into the circumstances connected with the disastrous fire at the Exeter Theatre, by which over 180 persons lost their lives on the 5th inst., have returned a verdict of "Accidental death." In riders appended to their verdict they expressed opinions to the following effect:—(1) That the magistrates are much to blame, and deserve censure for not having completed their inspection of the theatre, and for suffering themselves to be misled by the architect in the matter of the exit from the gallery to the second circle. (2) That it is a matter for regret that the Town Council's bye-laws do not allow of their efficient control over public buildings. (3) That it is deplorable that the architect, having been engaged as a specialist, should have produced such a building with so many structural defects. (4) That the architect failed in his duty in not providing a second exit for the gallery. (5) That legislation bearing upon the inspection and remodelling of means of exit, and the stage-working arrangements of all theatres, and the prevention of fires therein, should receive the earliest attention of Parliament. (6) That some effectual plan of excluding fire and smoke from the stage and other portions of the building should be adopted by the fixing of a water screen or other apparatus. (7) That the chief constable should be empowered to make inspection at all times of all parts of the building, without notice to the directors or to managers, and that he should make such inspection at least once every month when the theatre is open, and thereupon transmit a report of his inspection to the Town Council, and state whether all fire hydrants, ventilating apparatus, &c., are in perfect working order. (8) That before a magistrate's licence is granted for any public building, such building shall be thrown open, with all its approaches, entrances, and exits, to the inspection, under police supervision, of all householders in the borough for a week after its final completion.

LEICESTER AND VACCINATION.

Mr. J. T. BIGGS, in a letter to a contemporary, makes merry over the 100,000 persons in Leicester who are unprotected by vaccination from small-pox in defiance alike of the law and of common sense. What is especially gratifying to Mr. Biggs is that the contagion of this prejudice has spread to the more educated, or at least the wealthier, classes in Leicester. So that, whereas in ten years public vaccinations in comparison with births have decreased to the extent of 75 per cent., the decrease in private vaccinations is as much as 97 per cent. We are not inclined at this moment to disturb the peace and self-complacency of those persons who have allowed themselves and their children to get into such a state of exposure. We only wish at present to point out the inaccuracy of Mr. Biggs, whose statement will entirely mislead the public,

Digitized by Google

especially in one sentence, where he avers that in the last nine years there have been twenty-four importations of small-pox, the whole of which have been absolutely stamped out *by sanitary measures alone*. Mr. Biggs here implies that isolation, cleanliness, and disinfection have given the people of Leicester their immunity from the disease. We know this to be incorrect, and Mr. Biggs ought to know it too. Leicester is saved from the spread of small-pox when it occurs *by vaccination* just as all other towns are saved, and but for this much-abused operation the population of Leicester would soon be in a state of panic. When an importation of small-pox occurs in Leicester, the case or cases are visited by the sanitary authorities, the sanitary inspector, and medical officer of health, who to a man are vaccinated or revaccinated. The case is then forcibly removed to a small-pox hospital, all nurses and officials of which are revaccinated, unless they happen to have taken the clumsy Leicester method of protection by taking the small-pox. Not only so. Leicester authorities proceed to revaccinate every individual in the house in which the hideous disease has occurred, or who has in any way been exposed to the case. It is this cordon of vaccinated and revaccinated persons that saves Leicester. Without this all the boasted sanitary police arrangements would be mocked. If Mr. Biggs doubts this, let him ask the medical officers of the corporation of Leicester. If he thinks this cordon a delusion, let him get an unvaccinated staff of officials to receive the next importation of the disease he so underrates. If he agrees with us that Leicester's unvaccinated thousands are saved by the vaccinated few, he is ungrateful in not stating the fact.

THE DIGESTIVE FERMENTS.

IN an interesting communication to the *Pharmaceutical Journal* of August 20th, Mr. Schweitzer of Kansas City, U.S.A., states his adherence to the following conclusions: Pancreatine or pepsine (or the pig's stomach and pancreas) acts with perfect ease and freedom in presence of each other. When digested together they do not destroy each other, nor do they lessen each other's digestive activity in whatever proportion they may be digested. Long-continued exposure to heat and moisture injures their original activity. Digested in alkaline or acid solutions the injury is increased. Pancreatine when digested for some hours in an acid solution becomes permanently injured or destroyed, and pepsine when digested in an alkaline solution for some hours is also permanently destroyed. But a state of acidity (*sic*), such as the healthy natural secretion of the salivary glands, of the stomach, or of the pancreas presents, is not sufficient to interfere with any of their digestive functions.

TREE PLANTING AND DRAINAGE.

IT is not merely an æsthetic fancy, but equally a prudent regard for the health of the community, which has led civic authorities to plant with bordering trees many of the greater thoroughfares in towns and cities. By this arrangement the advantages of a purer air and of shade in warm weather are gained for the townsman, besides the implied increase of space and the amenity conferred by thus practically transporting a strip of country into town. It is one of the happiest features in the development of cities now so rapid, that in their outer and growing zone the hard lines of road, wall, and railing are interrupted at frequent intervals by spots of green sward and by the luxuriant foliage of climbing shrub and spreading tree. In so far we have learnt the lesson of experience, and, in thus preserving round our homes a healthy atmosphere and some degree of rustic beauty, are wiser for ourselves than the crowded cities of a former generation. Still, we are not always duly careful even in our wisdom, as the sequel shows. This very custom of tree planting in streets is open to a danger fortunately not common, but still grave enough to counteract, where it exists, the best effects of rural surroundings. It has happened repeatedly, as we are reminded by the letter of a recent writer on this subject, that the roots of trees in their growth have sought out the crevices of drain pipes adjacent, and penetrating these, have grown with such vigour on the nourishment which they found there as completely to choke the pipes and prevent the exit of sewage. We have here, of course, no argument against the continuance of the boulevard system, but certainly a caution, enjoining first the more perfect adaptation of drain segments, and secondly a kind of care not always observed in the relative arrangement of wayside shrubs and trees.

CHOLERA INTELLIGENCE.

LAST week we referred to the considerable extension of cholera at Messina, in Sicily. Since then there have been in the seven days ending the 19th instant no less than 665 fresh attacks and 265 deaths in the province generally, the greater part being apparently in the city itself. If the truth were known, it would doubtless transpire that the disease was prevalent in Messina before the date at which it was suddenly announced that the city was so gravely invaded; as it is, the epidemic is steadily maintained in the province, and on two occasions during the week under consideration the mortality has either reached or exceeded 50 a day. In Palermo a daily mortality varying from 3 to 10 is still continuing. No regular returns are received from other parts of Sicily, but the disease still prevails in different parts of the island, and whilst Messina is attacked to the extreme east, Trapani also suffers at its western extremity. On the mainland, the principal seat of the disease is in and about Naples, the deaths in the province of that name amounting to some 10 to 20 a day. Pozzuoli, Castellamare, and other places in the Gulf of Naples are especially mentioned as being still attacked. To the extreme south, Reggio, in Calabria, remains a seat of the epidemic; and it is rumoured that cases occur daily in Rome. There is, however, difficulty in ascertaining how far the attacks in the capital are cholera proper, or cases of severe diarrhœa, such as are met with in many large centres of population at this time of the year. In Malta, whilst cholera remains fatally prevalent, the disease shows no further signs of extension, and it seems still limited to the more destitute amongst the natives of the island.

MEDICAL EDUCATION FOR THE CHINESE.

DR. WYKEHAM MYERS is to be congratulated on the success that has attended his labours in educating Chinese youths in medicine. The movement is as yet quite in its infancy, but it has attracted a good deal of attention amongst both Europeans and natives in China, as it is hoped that from a very small beginning a great scheme of medical education for China will ultimately spring up. It has been found impossible as yet to give a really satisfactory medical education through the medium of the Chinese language, and so only students who have had a good Western education are accepted. Dr. Myers teaches in English. For the first of the two professional examinations, anatomy, elementary surgery, physiology, and chemistry are required. Great difficulty is experienced in teaching anatomy owing to the prejudices of the Chinese regarding dissection. It appears, however, that by means of models and plates the students have really contrived to learn their anatomy in a satisfactory way. Two examining boards have been established, in Hong-Kong and Shanghai respectively. Two students passed the primary examination in Hong-Kong last year, and one has

Digitized by Google

just passed in Shanghai. This young gentleman, Mr. Goh Kit Moh, was presented with his certificate at an important public meeting in Shanghai. Next year the two others who passed their primary in Hong-Kong last year will come up for their final examination in Shanghai, it being a rule that each student must pass his two examinations before different boards.

MARIANO SEMMOLA.

THE Italian papers are congratulating the distinguished Neapolitan physician on the *bella figura* he made at the Ninth International Medical Congress, all the more that his "record," as they point out, was already a brilliant one, on which it was difficult to improve. In 1883 his monograph on Bright's Disease, read before the French Academy of Medicine, evoked from that body a signal mark of approval and admiration. At the Congresses of Brussels, Amsterdam, London, and Rome, to say nothing of many other academic meetings in Italy and abroad, he never failed to contribute able and original matter to the proceedings. At the Sanitary Congress held in 1884 at Vienna he represented the Italian Government—represented it, moreover, so successfully that Max von Pettenkofer referred to him, in military phrase, as "my brilliant companion in arms." From Berlin he received gratifying attestations of the ability with which he spoke for the Italian view of debated points in medical theory and practice. His compatriots, not less proud of him as a benevolent citizen than as a learned and skilled physician, dwell on his indefatigable and fearless self-abnegation in the terrible explosion of cholera at Naples in 1884. Among his most cherished possessions is a portrait, in oil, of Louis Kossuth, "the Hungarian Garibaldi," as the Italians call him, a gift enhanced in worth for him by the following inscription, which stands engraven below it:—

Illustre Dottore Semmola,
Senatore del Regno,
che, profondo scrutatore
delle leggi del organismo umano,
coll' arte sublime
all' ottuagenario ridonò forze e salute
ricordo e pegno di riconoscenza
da
Luigi Kossuth.

(To the illustrious Dr. Semmola, Senator of the Kingdom, a profound investigator of the laws of the human organism, who, in the exercise of his noble profession, re-endowed the octogenarian with health and vigour, this picture is presented, as a memorial and pledge of gratitude, by Louis Kossuth.)

SEWAGE SLUDGE AS MANURE.

IT is satisfactory to hear of any successful agricultural experiments with sewage sludge. Our contemporary, the *Metropolitan*, reports that Mr. Joseph Jessop, of Pembury, near Tunbridge Wells, has obtained good results with pressed sewage sludge from Crossness. Mr. Jessop selected a poor sandy soil upon rock, and treated portions of it with sewage cake, farmyard manure, and artificial manures respectively. We are not told what quantity of each was used, or the relative weights of the crops obtained, which is unfortunate, for evidence upon these points would have been valuable. But good crops were obtained with the sludge, and Mr. Jessop is evidently satisfied, as he has already ordered 200 tons more of the material. The Metropolitan Board of Works are prepared to supply the pressed sludge gratuitously to all farmers who wish for it, and are willing to pay the carriage. We sincerely hope the experiment will succeed, for it is lamentable that so large a quantity of food-supply element should be wasted. It must, however, be remembered that repeated attempts of the same kind have been made ere this, and that the results have not on the whole been satisfactory. Pressed sewage sludge is by no means destitute of manurial value, but it is a weak manure, and cannot, as a rule, stand much cost of carriage. If used as a substitute for other fertilisers, it must be used in considerable quantity, and it is not suitable for all soils. The Metropolitan Board of Works, by their obstinate adherence to the present sewage outfalls on the Thames, have reduced themselves to the necessity of adopting the very worst system for the disposal of their sludge, and are actually arranging to take it in steamers down to the sea. If they can succeed in giving away any considerable portion something will be gained, although even then their sewage system will remain a disgrace to the metropolis. Fortunately the disgrace is so palpable that it cannot much longer be tolerated.

PLAY OF FEATURES AND MOVEMENTS OF LIMBS IN SICK CHILDREN.

ONE of the errors of too much specialisation is the tendency that exists in the specialist to believe that his own department more than any other is a fertile field for pathognomonic symptoms and signs of great diagnostic value. It is true that in some respects the diagnosis of disease in children is a more difficult matter than diagnosis in adults, but the difference is not nearly so great as some specialists would have us believe. The play of the features and the movements of the limbs are of considerable diagnostic significance in children and infants, but these signs cannot be said to be of no value in the adult, and it may be questioned whether their significance is very different in the two classes of patients. Soltmann has written anew, in the *Jahrbuch für Kinderheilkunde*, Bd. xxvi., p. 2, on the characteristic movements of infants suffering from various diseases, and his conclusions are very much the same as those usually recognised; at the same time it must be remembered that none of the positions given for various diseases are invariable. We demur to the general statement that in simple and tubercular meningitis there is a fixed expression as of deep thought which is quite characteristic; and we do so partly because such fixed expressions are frequently absent, though sometimes obvious enough, and partly from the difficulty which must have occurred to everyone to recognise "fixed expressions as of deep thought," though we admit that an immobility of the features is frequently present. Such statements as the following (in writing of meningitis) are, in our opinion, not warranted in the present state of knowledge: "When the optic chiasm is pressed upon, the eyes are rotated upward, the head is thrown backward, and the countenance expresses astonishment."

OVERCROWDING IN RAILWAY CARRIAGES.

So much is done in these days to secure the comfort of travellers by railway that one is hardly prepared to find that the primary necessity of sufficient accommodation still remains to a large extent a vain desire. No doubt there is something to be said for the embarrassment of companies like those in the metropolitan district when they find themselves on some periodic holiday overwhelmed by the uncertain rush of a multitude of sight-seers. The most perfect arrangements are not beyond the possibility of confusion. We are certain, however, that more might be done than is done to arrest that headlong assault on railway trains, without distinction of carriage or number of occupants, of which everyone has had some experience at times of general rejoicing. A more substantial reserve of third-class carriages available for holiday requirements is one chief desideratum. Another is a more frequent service, and in this direction the companies have certainly done something. Lastly, we would propose that, in order to infuse a little more energy into the direction of affairs on the

Digitized by Google

platform, the force of porters be augmented for the time being, either with additional help of the same kind or with that of specially enlisted non-official helpers. The forcible intrusion of persons often in the dirtiest condition among the occupants of first and second class carriages, who have purchased the comparative comfort in which they choose to travel, is a matter of serious public inconvenience. The company of these intruders is not only objectionable on æsthetic grounds, but it is equally undesirable on sanitary principles. Overcrowding is thoroughly unwholesome in itself. It is doubly so in the circumstances we have pictured, since the possible transference of infection and another *contagium vivum* of parasitic nature is no mere shadow of imagination when one's companions have come from the slums of a great city. In their own interest, and with the best intentions, we commend this subject to the notice and earnest consideration of railway directors everywhere.

MR. CHADWICK ON SCARLET FEVER PREVENTION.

THE veteran sanitarian, Mr. Edwin Chadwick, C.B., will have done good by his recent letter to the Association of Sanitary Inspectors if his accounts of the efficacy of cleanliness of person and surroundings lead to more regard to these important matters. But it is a pity that diseases having little or nothing in common, special and general rates of disease and of death, and such matters, are all mixed up together, and that the absence of scarlatina, whooping-cough, &c., should be attributed to a multitude of causes, as clean air, the removal of putrid sewage, clean bed linen, warmth, manual exercise, &c. A reader who knows how varying are the predisposing and exciting causes of the different contagia gets a little confused before he reaches the end of the letter; but all will hope that some good in the direction of increased cleanliness everywhere and under all circumstances may ensue as the result of the publication of the document.

THE ISOLATION OF INFECTIOUS PAUPERS.

AT Warrington the question whether the Town Council ought to receive paupers into their infectious hospital has been raised from time to time, and the guardians consider themselves aggrieved by the refusal of the Corporation to undertake this duty. Legally, we believe the Corporation can do precisely as they choose in the matter; but, on the other hand, there is no duty imposed on the guardians of the poor to act as an isolation authority and to deal with a pauper infectious case in such a way as to protect the public health; indeed, instances have occurred in which guardians have distinctly told sanitary authorities that, whilst they are prepared to do their duty in providing infectious cases with proper care and nursing, they decline altogether to remove them from their homes and to isolate them in the interests of the public. The Public Health Act defines the sanitary authority as the proper body to provide means of isolation for cases of dangerous infectious disorders, and it draws no distinction in this respect between paupers and non-paupers. Some day we expect every sanitary authority will be so desirous to prevent the spread of infection in their respective districts that they will not trouble to inquire, in a case of small-pox or fever, what is the social standing of the sick person. But at present this view is not very generally taken, and whilst some sanitary authorities look to the guardians to repay the cost of such pauper infectious cases in their sanitary districts as call for removal to hospital, others altogether decline to receive paupers. Even this latter course can be justified under existing arrangements, for many sanitary authorities have not sufficient accommodation to classify their patients according to their social status as well as according to disease. And no one will doubt that in many instances excellent work done by sanitary authorities would be materially hindered and checked unless such classification could be made in the case of paupers.

DEATH OF RICHARD QUAIN, F.R.C.S. ENG., F.R.S.

WE have to announce the death of Richard Quain, F.R.C.S., F.R.S., Surgeon Extraordinary to the Queen, which took place at his residence, 32, Cavendish-square, on Thursday, Sept. 15th. He was buried on Wednesday last at the Marylebone Cemetery, Finchley. The funeral service was conducted by his old friend, the Rev. J. D. Stewart, M.A. Amongst the mourners were General Mairis, the Hon. G. and L. Brodrick, Rev. P. Smith, Mr. Le Gros Clark, F.R.C.S., Dr. Rayner, General Cockburn, Messrs. Needham, Dickinson, Lawrence, and Walker. Next week we propose to give some account of the late Mr. Quain's professional work.

AN EXPERIMENT IN EARLY RISING.

AN interesting experiment is on foot in Lincolnshire, where, in the Wesleyan Day School at Hatcliffe, a summer time-table has been arranged, upon the plan of commencing school at 8 o'clock in the morning, and finally dismissing the children at 1.30. The result, so far, is reported as follows:—

"This school is situated in a purely agricultural district, and up to the beginning of 1885 the attendance during the summer months was very unsatisfactory. The work of the Third, Fourth, Fifth, and Sixth Standards was almost suspended from the 1st of May to the end of September, owing to absent children. It was almost impossible to reach a high standard of attainments. By the suggestion of Her Majesty's inspector, a summer time-table was tried in 1885. The school commenced at 8 o'clock, and finally was dismissed at 1.30, the meetings being 8 to 10.30 and 11.15 to 1.30. The average attendance increased from fifty-seven to sixty-three. The scheme has been tried again this year, and the average has risen to seventy, with the same number (eighty) on the books. Owing to the increased attendance, work has been continuous, and the pressure of the winter months has been relieved. Teachers and scholars worked much better in the cool early hours of the day. The health of the children greatly improved, and the result of the year's continuous work is the excellent merit grant."

The plan certainly deserves to succeed, and if its success should be sufficiently pronounced to stimulate imitation, so much the better. Late hours are to such an extent a necessity of adult life and urban conditions that we cannot hope to see any great change for the better in this respect in society at large; but it is important on the score of health and vigour, both of body and mind, that our children should become habituated to work in the early hours of the day.

ETHER INHALATION IN TETANUS NEONATORUM

DR. DEGHILAGE, of Mons in Belgium, having a case of trismus neonatorum, and having repeatedly given chloral and ether per rectum without producing any effect, the child rapidly becoming worse and seeming in imminent danger of death by asphyxia, determined to administer ether by inhalation. In addition to this, artificial respiration was employed from time to time by means of a tube inserted into the nostrils. Some pieces of Rigollot's mustard leaves were also applied to the chest. The child was laid on its side, according to a suggestion made by Marion Sims. The result of this treatment was that in a few hours the little patient's condition had improved to a very marked degree. The next day profuse perspiration occurred and the spasms entirely ceased. Shortly after this the child was convalescent.

A LEAP FROM THE CLIFTON BRIDGE.

AN inquest was held on Aug. 8th before Mr. Harwood, touching the death of a man aged thirty, who was killed by leaping from the Clifton Suspension Bridge. The case is interesting in that a post-mortem examination was made and the injuries carefully described. According to the evidence of Mr. G. E. Lloyd, the death occurred from shock. There was extensive bruising over the right side of the chest and over the left clavicle. The fourth, fifth, sixth, and seventh ribs on the left side were broken; and also the fourth rib on the right side. Both lungs were lacerated. All the cavities of the heart were empty. The liver and spleen were ruptured. The fracture of the ribs was due no doubt to the impact of the body against the water, for an eye-witness deposed that deceased when about sixty feet from the water turned over and fell upon his back, and the depth of the river is such that it seems improbable the body, falling flat, would reach the bottom. We commend the action of the coroner in directing an official inquiry, as it is said, "in the interests of the medical profession."

BERI-BERI AND BACTERIA.

A DUTCH observer whose remarks on beri-beri were noticed in a recent issue of THE LANCET, Dr. Pekelharing of Batavia, now announces that he has succeeded in cultivating the micrococcus of beri-beri. From his cultures he infected seven rabbits and four dogs, of which six rabbits and two dogs died in a longer or shorter period with symptoms of paralysis of various groups of muscles, especially of those of the posterior extremities and of respiration. On examination extensive nerve degeneration was found. In some cases the animals were infected by the injection of cultures obtained from the blood of beri-beri patients, and in others by a mixture of the bacteria existing in the air of a barrack where the disease had occurred.

DEATH, IN HARNESS, OF A CENTENARIAN PHYSICIAN.

DR. NEKLEWITSCH, of Loske in Poland, has lately died at the age of 109 years, having a quarter of an hour before his death seen and prescribed for a patient. Sixteen years ago he had a paralytic stroke, affecting both his feet, so that he has since that time been obliged to confine his professional advice to the consulting-room.

A COMPENSATION CASE.

UNDER the above heading we drew attention in our issue of the 10th inst. to the refusal of the St. Thomas rural sanitary authority to grant compensation under Section 121 of the Public Health Act for bedding and clothing destroyed in a case of alleged cholera at Newton-Poppleford. The Local Government Board, having been communicated with, have advised that the authority are not, under the circumstances reported, enabled to apply their funds in recouping the friends of the deceased. This is doubtless a correct legal view of the case, for the section requires that the local authority should "direct" the destruction of such articles as may be compensated for; and in this case neither they nor, so far as we can learn, either of their officers had to do with the destruction in question. Another time it would be advisable that the proper officers of the sanitary authority should be at once communicated with, and if a medical opinion is handed in to any such officer to the effect that the destruction of clothing or bedding is needed in the interests of the public health, it is highly probable that action would at once follow. Anyhow, all responsibility would then lie with the authority of the district in which the occurrence took place.

GOVERNMENT INQUIRY INTO THE SANITARY CONDITION OF BETHNAL GREEN.

WE understand that the Home Secretary has appointed Mr. D. Cubitt Nichols and Mr. Shirley F. Murphy to hold an inquiry into the sanitary condition of Bethnal Green, and that the proceedings are to commence at the Vestry Hall on Wednesday, October 12th, 1887, at 11 o'clock. The inquiry is the result of an appeal from the Mansion House Council on the Dwellings of the People.

ST. MARY'S HOSPITAL.

THE arrangements for the accommodation of students of the St. Mary's Hospital Residential College, at 33 and 35, Westbourne-terrace, have been extended. A large room is furnished as a general library, and additional studies are provided on each floor. Special tutorial classes will, we learn, be organised at the commencement of the winter session, by the warders, Dr. Walter Pearce and Mr. A. Pearson Luff.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Elias José Pediosa, Professor of Anatomy and Physiology in Bahia; Dr. Chastinet, editor of the *Gazeta Medica da Bahia;* and Dr. Don Juan Alvarado Gomez, director of the Ophthalmic Institute of Salamanca and editor of the *Correo Medico Castellano.*

TYPHOID FEVER AT DOWLAIS.

THE typhus epidemic at Dowlais is causing considerable anxiety to the sanitary authorities. There appears to have been a hitch in the nursing arrangements in the Fever Hospital—one of the nurses having contracted the disease soon after commencing her duties, and another having been overcome by panic and run away. Assistance had ultimately to be obtained from London. Later intelligence is to the effect that two of the nurses have succumbed to the disease, and that a report of the outbreak is being prepared at the request of the Local Government Board.

SOME of the members of Council of Hong-Kong are working hard at a Public Health Bill, which they hope to persuade the Government to adopt. The Chinese, fortunately, seem alive to the importance of the subject, and are actively assisting in working out the details of the Bill.

A VIENNA medical journal states that the vacation courses which have this year for the first time been organised have not been so great a success as could have been wished, a few of the classes only having been well attended, and these chiefly by foreign medical men.

WE are asked to state that Sir William MacCormac, in consequence of domestic bereavement, will be unable to take the chair at the Old Students' Dinner at St. Thomas's Hospital on October 1st, as announced in our advertising columns.

COURT SURGEON DITTMER, of Berlin, has just celebrated the fiftieth anniversary of his admission to the profession, which he obtained by the now obsolete diploma of *wundarzt* surgeon. The last of these diplomas was conferred in 1848.

DR. NEUSSER, who went to Bulgaria as body physician to Prince Ferdinand, has returned to his old appointment in Vienna—that of assistant in Prof. v. Bamberger's clinic.

THE Harveian Oration will be delivered by Dr. Stone at the Royal College of Physicians on Tuesday, October 18th, at 4 P.M.

THE SOCIAL ASPECTS OF THE INTERNATIONAL MEDICAL CONGRESS.

NOTWITHSTANDING that the City of Washington is, like most other cities, liable to suffer an annual desertion by the most influential part of its population during the early autumn, the ninth meeting of the International Medical Congress has been one of the most successful of its kind. We shall not err in saying that as a social undertaking merely, without regard to its professional aspect, this transatlantic gathering holds a place not second in importance to anything of a similar character that has happened, or is likely soon to happen, on that or this side of the dividing ocean. As an assemblage of medical practitioners and teachers in medicine met together with a common purpose of comparing and correcting the results of observation and invention, of devising new plans for future investigation, and of applying new modes of treatment in the art of healing, its significance is equally remarkable. With the single exception of London, no European capital has attracted so many representatives of medicine and surgery since the international movement first originated. Successful in point of numbers, the conference has not been less successful in possessing in more than one particular a thoroughly representative quality. It has been in the widest sense international. Almost every civilised people, besides races which might by courtesy be included in the same category, have contributed towards its membership. The four continents have given of the skill which is available for the treatment of disease in their civil practice, the military and naval services have subscribed each its quota of men and of material for discussion. Again, as regards the subject matter, it is almost superfluous to point out the illustrative diversities of study by which the sum of medicine can be viewed as through so many windows, and to state that each of these has received its full share of recognition in the working programme of the Congress. Last, but not least, the whole business and pleasure of this meeting have been administered throughout with a cordial good fellowship truly representative of that spirit of hospitality which happily characterises the American people and annually admits to the privileges of free citizenship strangers out of every country without distinction. President Cleveland and his assessors in the work of Government have been foremost in showing attention to the American practitioners and their guests. Not only have they taken an active part in the extra professional work of the Congress, but it is through their influence that Government buildings have been on several occasions available for social gatherings of the members. We are happy to recall the fact that in so doing they have but revived the precedents afforded by the conduct of other States, but we appreciate no less on that account the warmth of their generous consideration. Nor must we forget to offer an equal tribute of esteem to the American medical press, and to those citizens of Washington who distinguished themselves by affording a similarly handsome hospitality.

There are certain definite advantages connected with such conferences as that which is just over, and these may well occupy our attention during the remainder of the space at our disposal. Some, perhaps, may question their utility on the ground that an exchange of views is, in matters of mere knowledge, as easily possible by ordinary channels of publication. This argument we need not now stop to discuss. The advantages to which we have alluded are only in part such as can be attained by means of the printing press. We may discuss them, as they affect medical men themselves, the general public in their relation to practitioners, and, lastly, entire nations. To a member of the class first mentioned the atmosphere of free discussion is helpful in several ways. In it he is able freely to communicate and compare ideas, and to question directly the exponents of theories or methods in which he is interested—no small benefit in a profession like our own, in which demonstration is everything for purposes of instruction. He is better able also, in concert with others, to arrange plans for combined action with regard to a given subject. Take, for example, the system of collective investigation as applied to disease. Whatever may be the total results of that mode of research, it cannot be denied that there is truth in the remark made by Dr. Nathan S. Davis, the president at the late Congress, that in order to explain many of the phenomena of disease the intelligence of well-informed general practitioners is required, and that the plan of conjoined investigation, with the assistance of the check imposed by a central and critical authority, is calculated to utilise this intelligence. It is probable, however, that no greater good is conferred on the individual worker by association with his fellows than the stimulus to friendly and wholesome rivalry. Labouring alone and striving through repeated failures to explain the unknown, he may find himself often unduly sobered by the shadow of the uncertainties which confront him. United with others who share his experience, but arrive at last in the open light of certainty, he is fortified by hope, and, carried forward by an invigorated confidence, reaches in time the desired end of his efforts. The success of others has an infection about it, and it is well, therefore, to place oneself within its influence. Let us, too, before we leave this subject, remind ourselves how greatly the recreation and good fellowship with which the leisure intervals of all such meetings abound can refresh both mind and body, and we will no longer doubt that in this respect they have their value. But the non-professional public also profit in illness by the congresses of their advisers, and this directly. They are thus enabled, we may say, to make friends with the medical fraternity, and to know them better as a class. They are in a measure taken into confidence, so to speak, and through newspaper reports can follow with understanding no insignificant part of such debates as do not require much technical training for their apprehension. The public well-being is benefited by the reception of such filtered knowledge, provided this does not engender a spirit of presumptuous self-confidence, and this it will not do in the mind of any sensible reader. The consequences of this better understanding of general principles is to make the person instructed a more intelligent patient in illness, to engender a generally better acquaintance between the invalid and his adviser, and to aid the formation of a true estimate of the value of medical service. Furthermore, those who may have noted in the diversity and disparity of qualifications, in varieties of treatment, and in the jealousies of individuals which at times disturb the current of professional unity, only so many evidences of disagreement, have in meetings such as that which has just ended overwhelming proof that the body of medicine remains, notwithstanding, substantially one whole. Mr. Bayard, Secretary of State, in his opening address, dilated on the benefits of international intercourse, and rejoiced that there is among men of all nations a sense of brotherhood which is tending more and more to assimilate them in spite of the distinctions imposed by geographical separation. He viewed the Congress in its unprofessional aspect as an expression of this feeling; and such, indeed, it was. It is not certainly to be expected that meetings of this kind, however universal in their membership, however influential, will rapidly remove the barriers of racial difference, fortified by national interests and the political forces by which these are naturally and justly supported; but there is good hope, notwithstanding, that they will gradually effect at least a salutary modification of that difference. Men cannot meet together to consider measures of sanitary precaution and means of cure which are applicable in every quarter of the globe without in some degree losing sight of their narrow personality, even their nationality, in grasping as they firmly can the real and wider, if less definite, consciousness of a common good for all, which they may peacefully strive after and peacefully enjoy. It is our happiness to reflect that in the early dawn of that still shadowy peace the profession whose function is the relief of pain in mind and body has been well committed to the work of reconciliation. Such and other truly civilising efforts may encourage us in the conviction that He who through all hindrances and apparent contradictions seeks the final good of the world He has created, will one day guide mankind into that state which one of our own countrymen has foreseen and prefigured in words of classic beauty and prophetic force—wherein

HEALTH OF THE ARMY.

No. II.

THE strength of European troops in India during the year averaged 57,165; the admissions into hospital were 1522; the deaths, including those of invalids on the passage home, 15·18; the invalids sent home, 22·79; and the constantly sick 70·58 per 1000. With the exception of the invalided to England, these ratios are all higher than in 1884, and the admissions and mean sick are above the average of the last ten years. The distribution of the sickness and mortality in the three Presidencies were as follows:—

—	Average annual strength.	Ratio per 1000.			
		Admitted.	Died.	Invalided home.	Constantly sick.
Bengal	35,101	1649	13·61	20·34	73·17
Madras	10,414	1162	9·79	24·10	65·87
Bombay	11,650	1460	24·72	29·01	67·00

This summary shows Madras to have been the most healthy of the Presidencies; and, although Bengal furnished the highest proportion of admissions and mean sick, Bombay had much the highest death-rate—results which accord with those of 1884. In Bengal the admissions corresponded very closely with those of the preceding year, but were considerably above the average of the decennial period, the excess being chiefly in syphilis, gonorrhœa, and injuries, while there was a decrease in fevers and in diseases of the digestive system. The deaths were slightly higher than in 1884, but above 5½ per 1000 under the average of the last six years, the reduction being chiefly in cholera and in diseases of the digestive and nervous systems. The admissions into hospital in the different military divisions ranged between 2422 in the Meerut and 1258 in the Rawal Pindi. The highest ratio at any station was 4156 per 1000 at Delhi, and the lowest 1015 at Ranikhet. The death-rate was highest in the Meerut division, amounting to 17·33, but was nearly the same in the Allahabad, and it was lowest in the Rohilcund division, being only 9·45 per 1000. The highest ratio at any station was 41·78 at Muttra; at Jhansi no death occurred, and at fifteen stations it was under 1 per cent. The admissions by eruptive fevers were greatly above the average, owing to the prevalence of dengue at Lucknow, Umballa, Calcutta, and Fyzabad; there were altogether 726 cases, but no deaths. Enteric fever was the cause of 486 admissions and 142 deaths, being in the ratio of 13·8 and 4·05 per 1000 respectively. The stations at which it was most prevalent were Allahabad and Cawnpore in the Allahabad division, Lucknow, Sitapur, and Fyzabad in Oudh, Morar in Gwalior, Meerut and Muttra in Meerut, Meean Meer in Lahore, Rawul Pindi, and Cherat in the Peshawur division. Only 1 case occurred among troops on the march, and 2 in the camps of exercise. The disease was most prevalent in the third quarter of the year. Lucknow was the station which furnished the greatest number of cases, there having been 55 admissions, but with only 10 deaths. The medical officer in charge states that "in no instance could the disease be traced to insanitation, or to faults in connexion with food or water." At Morar there were 30 cases and 11 deaths; "It was not possible to assign any cause for the disease; no sanitary defects of any importance were observed, the milk and water supplies were carefully attended to, and the prevalence of the disease, in the opinion of the medical officer, could only be attributed to climatic causes and to individual susceptibility." At Cherat defective latrine arrangements were considered to have been in some degree a cause of the disease, and at Sitapur an insanitary condition of one of the barracks was assigned. At most of the stations, however, it was found impossible to determine anything definite on the subject. The cases occurred mostly, though not exclusively, among young soldiers with a short period of residence in India. Paroxysmal fevers were the cause of nearly one-third of all the admissions into hospital, but were not of a very fatal character. The troops were remarkably free from Cholera during the year, only 61 cases having been admitted; but of these 37 died. It was pretty widely spread, but the greatest number of cases at any one station was 7 at Lucknow, and of deaths, 5 at Fortress Gwalior. Thirty-six of the cases and 22 deaths occurred in the third quarter of the year. It is not stated what precautions were taken on the appearance of the disease at any of the stations except Allahabad, where after the occurrence of 5 cases "the troops marched out and the disease ceased." There was a considerable increase in the cases of syphilis, especially in the Rawal Pindi, Allahabad, and Presidency circles; the only divisions in which there was a decrease were Saugor and Gwalior. There was also an increase of gonorrhœa, most marked in Peshawar and Saugor. Under diseases of the nervous system 80 cases of sunstroke were admitted, with 26 deaths, and there were 3 fatal cases of hydrophobia, 2 at Dum Dum in men who had been bitten by the same dog, and 1 at Umballa. Dysentery and diarrhœa gave rise to 81 admissions and 0·37 deaths, and hepatic disease to 21 admissions and 0·88 deaths per 1000 of the strength, the admissions being somewhat under, and the deaths about half, the average of the preceding six years. Under the head of poisons, 324 admissions and 7 deaths were recorded from the direct effects of intemperance, being in the ratio of 9·3 and 0·20 per 1000; the only other case was one of opium poisoning, which recovered. The deaths from injuries were in the proportion of 1·36 per 1000, which closely approximates the average.

The sickness and mortality in the different arms of the service in the Bengal command were as follows:—Cavalry, 1962 admissions, 17·01 deaths, and 83·1 constantly sick per 1000 of strength; artillery, 1751, 10·67, and 79·90; infantry, 1635, 12·52, and 71·05 per 1000. The cavalry therefore seem the most unhealthy, the artillery have the lowest death-rate, and the infantry the least amount of inefficiency from sickness. The distribution of the mortality and invaliding in the different grades is shown in a table in the appendix to have been—death-rate of officers 11·27, non-commissioned officers 18·47, privates 14·35; and the invaliding of officers 50·30, non-commissioned officers 18·23, privates 19·72. It is very probable that the lower death-rate of the officers may, to some extent at least, be due to the greater facilities afforded them for invaliding, while the higher rate of non-commissioned officers as compared with privates may be a result of their more advanced age. The mortality of the women during the year was 13·29, and of the children 53·04 per 1000. Convulsions were the most frequent cause of death among the latter, having given rise to upwards of one-fifth of the whole. There were only 2 deaths by cholera among the women, and the same number among the children.

The only serious complaints of sanitary defects appear to be one of the impure water supply at Dum Dum, and another of the very unsatisfactory construction and insanitary condition of the Sanatorium at Cherat. Recommendations on both of these points have been made, which it is trusted may be carried out with beneficial results.

In Madras there was an increase in all the ratios except invaliding compared with those of 1884, but they were all under the average except the constantly sick, which shows an increase of above 5 per 1000. The admissions in the different military circles ranged between 995 in the Belgaum and western district and 1228 in Burmah, the highest ratio at any station, omitting the depots, being 1461 at Toungoo. The deaths were from 2·91 in the Nagpore circle to 12·66 in Burmah, and the mean sick from 54·26 in the Nagpore to 86·35 per 1000 in the eastern district. There was a decrease in fevers compared with 1884, and they were considerably under the average of the last six years. The Nagpore force furnished much the highest proportion of cases, owing to the prevalence of paroxysmal fevers, but it had the lowest death-rate from this class. There were 73 cases and 23 deaths of enteric fever, being in the ratio of 7·0 and 2·21 per 1000. Secunderabad was the station at which it prevailed most, there having been 29 cases and 10 deaths; Bangalore had 18 cases with 1 death, and Bellary 8 cases and 2 deaths. At Secunderabad no insanitary condition could be traced in the barracks, and the disease is believed to have been "contracted in some of the villages situated close outside cantonments, which are generally in a filthy condition." At none of the stations could the origin of the disease be traced to any definite cause except at Calicut, where it was believed to be an impure condition of the water-supply. A case at Cannanore and one at Toungoo were attributed to "bad water drunk on the march." Of cholera, only

Digitized by Google

6 cases and 2 deaths occurred, 4 with a death at Secunderabad, 1 fatal case at Kamptee, and one which recovered at Toungoo. Venereal diseases were considerably above the average, the highest ratio being 411 in the Bangalore circle and the lowest 217 in Burmah.

The sickness and mortality by arms of the service were—in the cavalry, 1140 admissions, 6·76 deaths, and 58·56 constantly sick per 1000 of strength; in the artillery, 1181, 9·11, and 65·13; and in the infantry, 1155, 8·46, and 63·24. The cavalry, therefore, were, in all these particulars, the most healthy and the artillery the most unhealthy. The deaths and invaliding in the different grades were as follows:—Officers, 7·71 deaths, 51·41 invalided; non-commissioned officers, 18·47 and 41·76; and privates, 7·66 and 20·61 per 1000 of strength. As was the case in Bengal, the death-rate of the non-commissioned officers was much higher than of the privates, and the invaliding of officers much above that of the other grades; the death-rate of officers and privates corresponds very closely. The mortality of the women was 13·33, or almost identical with Bengal; that of the children was 31·87 per 1000; there was one fatal case of cholera in each class.

In Bombay the admissions, deaths, and mean sick were higher, but the invaliding slightly lower, than in 1884; the deaths and mean sick were greatly in excess of the average. The highest ratio of admissions (2206) was at Quetta and the lowest (1071) in the Presidency circle. The deaths ranged from 85·23 at Quetta to 10·90 in the Poona circle; the lowest death-rate was at Ahmednagar, where it only amounted to 2·18 per 1000. The excessive sick-rate at Quetta was due to paroxysmal fevers, and the death-rate to cholera and dysentery. Enteric fever was the cause of 88 admissions and 30 deaths, being in the ratio of 7·6 and 2·57 per 1000 of strength. Kurachi was the station at which the greatest number of cases (19 with 4 deaths) occurred; Deesa and Quetta had each 14 cases and 4 deaths, Nasirabad 10 cases and 4 deaths, Poona 8 with 5 deaths, and Belgaum 7 with 4 deaths. At none of the stations could the disease be traced to any insanitary conditions in or near the barracks, or to the water supply. "The disease is said to be endemic in the city of Kurachi, and is in great measure due to the cesspool system in vogue there." Paroxysmal fevers were the cause of the highest ratio of admissions into hospital, amounting to 450 per 1000 of strength. Quetta was the station at which they were most prevalent, the ratio being as high as 1178, and the deaths 4·32. The Presidency circle had the lowest ratio. Of cholera there were 131 admissions and 85 deaths, being in the ratio of 11·2 and 7·30 per 1000. There were no cases in the Poona circle; the only station in the command at which it prevailed to any extent was Quetta, where there were 103 cases with 67 deaths in an average strength of 1619 men, or 63·62 and 41·38 per 1000. There were 14 cases and 8 deaths among troops on the march. The first case in the Quetta Valley was on June 3rd in the 1st Oxford Light Infantry, and the last case occurred in October. Notwithstanding numerous removals, the disease continued in this regiment until it finally quitted the valley. The death-rate of the corps during the eight months it was in the Quetta Valley was 129·54 per 1000, but the information is not given in sufficient detail to enable us to state the proportion due to cholera and to fever or other diseases respectively. The death-rate of the other infantry regiment at Quetta, the 1st North Lancashire, for the year, was 56·78 per 1000, while that of the Royal Artillery was 41·01 per 1000. Diseases of the digestive system were the cause of a high death-rate (5·06 per 1000), though the admissions were under the average of the preceding six years. The excessive prevalence and mortality chiefly took place in Quetta, where the cases amounted to 311 and the deaths to 19·76 per 1000 of strength, the latter mostly from dysentery. The admissions from the direct effects of intemperance—delirium tremens and alcoholic poisoning—were in the proportion of 9·56, and the deaths of 0·60 per 1000.

The relative sickness and mortality in the different arms were: in cavalry, 1221 admissions, 6·71 deaths, and 65·9 mean sick; artillery, 1446, 16·46, and 65·5; and infantry, 1690, 26·85, and 72·6 per 1000; so that, as in Madras, the cavalry were the most healthy. The excessively high rates in the infantry were the result of the large number employed in the Quetta Valley; and the low death-rate of the cavalry may be accounted for by their not having been stationed in that pestilential district. The deaths and invaliding of the different grades in the Bombay command were: deaths of officers 16·44, non-commissioned officers 31·59, privates 22·87 per 1000; invalided—officers 68·5, non-commissioned officers 43·8, privates 26·7. The same feature therefore is observed, as in other Presidencies, in the high rate of deaths of non-commissioned officers, and the much lower rate, but with a high one of invaliding, among the officers. The death-rate of the women was 12·82 per 1000, which corresponds very closely with that of Bengal and of Madras; and of the children it was 53·40, the same as Bengal, but considerably higher than Madras.

The report on the health of the troops in Egypt includes those quartered in Lower Egypt for the year—the Frontier Field Force from Aug. 1st to Nov. 25th, and the garrison of Suakim from May 15th to the end of the year. The details of the Frontier Field Force and the troops at Suakim in the earlier months were given in the department volume for last year. The average strength of the force was 9593, the admissions were in the ratio of 1522, the deaths 28·98, and the mean sick 80·23 per 1000. The incidence of sickness and mortality was much greater in the small force at Suakim than in the other two divisions. Enteric fever was the cause of 497 admissions and 136 deaths in the whole force, or in the ratio of 51·8 and 14·18 per 1000 of strength, the latter amounting to half the death-rate of the command. The highest proportion of cases and deaths by this disease occurred amongst the troops at Suakim, and the next in the Frontier Field Force; of the cases in Lower Egypt, many were believed to have been contracted at Suakim or on the Nile expedition. The disease is stated to be endemic along the whole Nile Valley. At Suakim "there is no evidence connecting the occurrence of enteric fever with contamination of the water supply or food"; but in Lower Egypt "the insanitary condition of the towns is so bad that it is not surprising that men suffer severely from this disease, notwithstanding that every precaution is taken in barracks." It is noteworthy that the men confined in the military prison enjoyed a marked exemption from enteric fever, only one case having occurred in an average of over 60 prisoners. Paroxysmal fevers occurred almost entirely among the troops in Lower Egypt, and especially in the 2nd Battalion, Sussex Regiment stationed at Suez. "It happens that the camp at Suez is very low-lying, water being obtainable only two feet from the surface, and the whole of the land in the country is wet on account of irrigation and percolation from the fresh-water canal which passes close by. The inhabitants of Suez suffer from these fevers every autumn. There is practically no malarious disease in the other stations in Lower Egypt"; but as regards Suakim, "there can be no doubt that the station is, as might be expected from the condition of the soil and drainage, distinctly malarious." Syphilis and gonorrhœa were a cause of great inefficiency in Lower Egypt, the admissions having amounted to 370, and the constantly non-effective to 23·35 per 1000. They were much less prevalent in the other two portions of the force. Sunstroke and exhaustion from heat gave rise to a very large number of admissions and deaths at Suakim, the former having amounted to 60, with 15 deaths, and the latter to 216. "The Principal Medical Officer remarks that the insufficient protection from the intense heat of the sun during the hotter months afforded by tents, was probably to a considerable extent accountable for this; but he thinks that the excessively high temperature in conjunction with the moisture and the stillness of the air would probably, however, with the best possible accommodation be largely productive of these conditions." No cases of cholera occurred during the year. Diseases of the digestive system furnished the highest ratio of admissions, and also, with the exception of fevers, of deaths, the most prevalent diseases being diarrhœa, dysentery, dyspepsia, hepatic affections, and tonsillitis; dysentery was the most fatal. There was a death from poison, caused by chloroform which was being administered for the performance of an operation.

The following extract from the report of the sanitary officer sufficiently accounts for the very high ratios of sickness and mortality among the troops quartered at Suakim. "The ground in the neighbourhood of the town is extremely polluted. Owing to the very slight elevation of the land, only a few feet above the sea level, there is no outfall for drainage, and the long neglect of sanitary precautions by the natives has led to the soil becoming saturated with filth of various kinds. The water in the harbour rises and falls at irregular intervals, the variation in its level being apparently dependent on the direction of the wind. The low-lying land to the west is thus frequently inundated, and on the subsidence of the

Digitized by Google

sea presents an extensive surface of organic decomposition. Under the same circumstances the sloping coral reefs to the south, alternately covered and exposed to the sun, emit offensive organic effluvia." To this must be added the intense heat and the inadequate protection afforded to the troops by tents.

In an average strength of 344 officers the admissions were 1235, the deaths 26·16, and the invalided 238 per 1000, "the latter being greatly increased by the effects of the Suakim and Nile campaigns."

From the table showing the sickness and mortality by corps, we find that the admissions were, in the cavalry 1909, artillery and engineers 1547, infantry regiments 1523, departmental corps and staff 1214 per 1000; and the deaths were 45·45, 38·97, 24·80, and 47·62 in the arms respectively. The departmental corps and staff, therefore, had the lowest ratio of admissions and the highest of deaths, while the proportion of both was higher in the cavalry than in the ordnance and infantry.

HYGIENE IN THE SCHOOL ROOM.

GREAT as has been the advance made in recent times in a general appreciation of the value of preventive medicine, there still exists widespread ignorance and consequent apathy on many points of vital importance to the community at large. Nowhere is this more conspicuous than in the school room, where, notwithstanding the lively interest which the work of education awakens at the present time, insalubrious conditions exist sometimes to a positively shocking extent.

These reflections are suggested by the general tone of the recently issued Education Report. "It is time to attempt some further progress lest we go back," is the language of one of the chief inspectors, and it not inaptly expresses the general drift of comment. This would be highly satisfactory and very laudable if the solid facts of the case justified such a rose-coloured view of the nature of our actual achievements. But we strongly suspect that we are much nearer the beginning than the end of our task, and that the directions in which improvement must be sought are sufficiently obvious to call for energetic effort without the somewhat artificial stimulus of a dread lest we should lose the ground already gained. To school managers throughout the country, and especially to the central department, which, by its elaborate organisation, exerts an enormous influence on the national education, we commend a few points well fitted and well worthy to tax their endeavours for some time to come.

WARMING AND VENTILATION.

To these two closely connected and most important features of school-room hygiene the references throughout the report are extremely few and meagre. But such as they are, they show conclusively that the prevailing condition is highly unsatisfactory. "It is still," writes one inspector, speaking particularly of the north of England, "quite a common thing at visits without notice to find the air of schools, especially in the class rooms, unwholesomely close." The evil, however, is by no means confined to the north. Even more emphatic is the testimony of the chief inspector for the Welsh division. "The ventilation of schools," he says, "is seldom good"; and he casts the blame partly on the appliances supplied, but in part also upon the teachers, who often fail, in his view, to turn such appliances as they have to good account. As to the latter part of this complaint, there ought to be no difficulty whatever in finding a remedy for the mischief complained of. A due appreciation of the importance of the point on the part of inspectors and managers would soon arouse teachers to a sense of their duty, and the judicious distribution of a few thermometers would not only give a business importance to the regulation of temperature, but would also enable visitors to exercise a much more effective supervision than is at present possible. It is easy to understand that when the inspector thinks a room over-heated, or unequally warmed, or at too low a temperature, or insufficiently supplied with fresh air, the teacher may entertain an opposite opinion, and as the teacher is always in command, while the visitor's authority is very transitory, it is the teacher's view which must generally prevail. On this footing it will be a hopeless task to attempt effecting improvements; but much might be done by the simple expedient to which we have alluded. Thermometers will not, indeed, disclose all that it is worth while to know respecting even the warming of an apartment. But two instruments, suitably placed, so as fairly to exhibit the extremes of temperature to which occupants of any room are exposed, will always be a valuable addition to its furniture, and, seeing that thermometers are inexpensive, we think that these should be an indispensable part of the equipment of every school room.

Even in the matter of stoves, although the difficulty looks more serious, the appearance is greatly worse than the reality. The obstacle to improvement in this respect is, of course, the financial one. But that is in a large degree imaginary, for an inefficient stove is a most wasteful contrivance. The cost of substituting something better may be recovered many times over in the consequent saving of fuel. No doubt in many places there are buildings in use for school purposes so incorrigibly bad that nothing short of reconstruction would suffice to make them reasonably fit for occupation. In such a case the renovation must no doubt be a work of time. But where it is only a question of replacing an open grate, or making, at a small outlay, some improvement in the heating apparatus, we think that the central authorities might usefully bring pressure to bear upon reluctant managers, for not only would the hygienic conditions of the school be improved, but also, in most cases, a considerable and more than commensurate saving in the cost of fuel would be effected. A little assistance to the local imagination in grasping a fact like this is often the best service that the central authority can render. How much this whole subject needs bringing forcibly to the attention of school managers is well illustrated by the case of the Eccleston School Board. The members of this Board, with the most commendable zeal, take upon themselves the duty of inspecting the schools under their management. On these occasions the visitor is provided with a schedule of questions directing his attention to the various points which he is expected to observe, and these questions with his answers he files after the visit. Of this plan it is impossible to speak too highly, and of the schedule itself it may be said that it has evidently been drawn up with great care, and is in many respects an excellent production. But although it travels over the field of hygiene, and puts such questions as "Does the heating apparatus act efficiently?" there is no reference at all to the temperature or ventilation of the school or class rooms. "If these things are done in a green tree, what shall be done in the dry?"

APPLIANCES.

Another point to which the majority of the inspectors do not seem to be keenly alive is the defective nature of the appliances with which most of our schools are fitted. Desks are made unsuitable both in size and shape. Windows are rendered needlessly hideous with ground glass, and sometimes so situated that it is impossible to obtain an incident ray from the proper angle for writing by. These points are so well put in Mr. Blakiston's report that we gladly avail ourselves of his statement of them:—

"At a properly constructed desk, the lower edge of which overlaps the seat from one to two inches, at a height sufficient to allow the forearms to rest horizontally, and where a rail attached to the back of a broad and hollowed seat supports the loins, writing may be done for an hour or more at a stretch without any sense of discomfort, or any injury to eyesight or spine, if an upright position of the body be maintained, and if the writer keep his elbows by his sides and his pencil or pen pointed to his right shoulder. Unfortunately many thousands of our schools are supplied with desks made with utter disregard to the comfort and health of the scholars. The seats, flat rails some six inches broad and without back rests, are fixed so far from the desk for ease of ingress and egress, that in writing the children sprawl on the desks with elbows out, bodies forming an angle of 45° with the bench, twisted spines and contorted shoulders, the head often resting on the left arm, both eyes too near to the paper, and the left eye nearer than the right. Very often the height of the benches suggests that they have been supplied for the comfort of adults on Sundays and in evening meetings, to the consequent discomfort of the children, whose legs dangle restless during the week-day sittings. In planning schools it is of great importance that light should be duly admitted on the left shoulders of the children. If the light come from the south, blinds should be so arranged as to be drawn *upward*, so as to exclude the dazzling rays from the eyes, but not to darken the upper air of the room. Non-transparent glass, the use of which throughout spoils many a good school room, should be used only in the lower panes, and that only where a school can be overlooked from without. Where it has been found impossible to rearrange desks so as to have the light from the left, the insertion of fixed skylights on the northern slope has in hundreds of cases made it possible to secure the best light and to carry on school work that had been before impracticable in dark hours."

Elsewhere another inspector writes—not, surely, without reason: "I think the subject of desks and their position in the school demands serious attention."

INFECTIOUS DISEASE.

It might be supposed that if there is one branch of school hygiene which is universally understood, and about which there is an absolute consensus of opinion, that point is the treatment of epidemic disease. Yet such is the prevalent supineness in relation to this matter that we find an assistant inspector, Mr. Myers, in the course of some very interesting and valuable remarks on the waste involved in school epidemics, pleading for the simplest and most obvious precautions against infection. "I am not," he writes, "pressing for any specific enactment on the matter. I think, indeed, that school boards and school attendance committees should require (and perhaps in some cases pay for) a medical certificate of non-infectiousness before a child who has been ill in this way returns to school." We quite agree with him, and trust that, without waiting for Parliament to move, the Education Committee will take steps to bring this elementary lesson home to the local authorities all the country over. It is appalling to think how unrebuked carelessness in a matter such as this may daily promote disease; how vast the number may be of children needlessly exposed for lack of the simplest precautions to peril of their lives; and how large an aggregate of sickness and death may be traceable to such easily preventable causes. Upon the whole, then, there is plenty of work for the department at present, if only in the development of school-room hygiene. Alexander may spare his tears, for a whole world still awaits conquest at his hands.

SANITARY INSTITUTE OF GREAT BRITAIN.

THE Annual Congress of members of the Sanitary Institute of Great Britain was opened at Bolton on the 20th inst., under the presidency of Lord Basing.

The first item in the day's proceedings was a reception by the Mayor, Mr. Alderman Fletcher, at the Town Hall, where they were afterwards entertained to luncheon. An exhibition of sanitary appliances and apparatus which is held in connexion with the meeting of the Congress was afterwards opened by the Mayor in the Drill Hall, and subsequently the members visited a number of public buildings and other places of interest in the town. The first general meeting was held in the Albert Hall in the evening, which was largely attended.

Lord Basing, in his address, briefly reviewed the history of the statutory and other steps which had been taken of late years in relation to sanitary science, dwelling especially upon the work of the Royal Sanitary Commission. After analysing the work done during the last few years by the Local Government Board, Lord Basing recapitulated some of the amendments which have been proposed to the Public Health Act, 1875, and stated that he felt bound, as the final result of his experience, such as it had been, to say that, having regard to the comparative novelty, to the difficulty and obscurity of the subject, to the dislike of control, and to the great expense attending works of sewerage and water supply—still more, when we remember the disinclination of Parliament to turn aside from the more stirring and generally interesting matters which make or mar the fortunes of Governments and parties, he felt more than satisfied, on looking back over a period of thirty years, to find that so much has been really accomplished. At this moment his apprehension undoubtedly was that in the anxiety to escape the irksomeness of detail, and in the hurry to establish local government generally on a wider and more popular basis, mischief may unwittingly be done through misappreciation of the difficulties under which that which now exists has been built up, and of the great risk which may be run if such central control as is really still required were to be hastily surrendered. Lord Basing concluded his address by quoting the illustrations of progress which had been given by Mr. Edwin Chadwick.

After the delivery of the address, a cordial vote of thanks was passed to the President, and the meeting adjourned.

At the meeting of the Congress on the 21st inst., the address to Section 1, on "Sanitary Science and Preventive Medicine," was read by J. Russell Reynolds, M.D., F.R.S., Emeritus Professor of Medicine in University College, London. He observed that the causes of disease with which preventive medicine has to deal are so numerous and so various that it was first of all necessary to arrange and classify them in some logical order. This he attempted to do, pointing out that the devices that must be employed to prevent the development of further progress of inherited disease are as manifold as the affections themselves. On this head he remarked—first, there is no disease that has yet been shown to be always hereditary in its origin, so that when we meet with insanity or phthisis in an individual we are not at once to conclude that it was "inherited" because a parent had been epileptic or a grandparent had died of consumption. A large proportion of hereditary diseases can be traced to no hereditary source in particular individuals. Therefore we must allow that in a large number of cases where the possibility of inheritance is patent a certain number may have developed the disease *de novo*. Secondly, with regard to many, the anti-hygienic conditions and habits which have led to disease in ancestors may be persistent as cherished heirlooms and be effective for mischief now. Especially is this the case in respect of the large group of diseases of the nervous system. There is much more than the mere physical contamination by descent in the etiologic conditions of a boy or girl who may be brought up in constant association with an idle, self-indulgent, hypochondriacal, or drunken father; and it is quite impossible to over-estimate the dire misfortune to a girl of being educated by an hysterical mother. No high powers of the microscope are needed to discover the *modus operandi* of the *materies morbi* of the contagion of bad example. If there are occasional examples of hereditary "nervousness" or simple epilepsy, there are also of tubercle, scrofula, Bright's disease, and others, about which it may be truly said "the whole head is sick, the whole heart is faint, and there is no soundness in it." Yet even in extreme cases preventive medicine has its work to do. The condition of ill-health most frequently met with in hereditary diseases of the nervous system is one of undue liability to disturbances given in any one of the antecedents of a particular individual, either insanity, epilepsy, hysteria, tendency to excesses, great nervousness, or what not. The outcome may be any one of the maladies mentioned, not being at all necessarily a reproduction of the initial disease. It is by bearing this fact in mind that the physician will see the necessity of being armed at all points. It is not enough to avoid or counteract the tendency to convulsions in the first dentition and the second or third; but chorea, hysteria, wilfulness, tricky ways, cruelty, and deceit must be borne in mind. No routine practice will be useful; it is often worse than useless. In some subsequent observations on sexual difference, Dr. Reynolds said it is worthy of note that it is not the highest qualities of man that young women imitate, but rather, on the one hand, the roughness of the youth, his bravado and uncouth language, or, on the other, the lackadaisical, *nil admirari* tone of the pedant and the fop. With it may be an occasional dash into imitation of excessive learning and the habits of the ascetic or recluse. The men who mock women's ways also mock their foibles, not their strength, and lisp and sigh or groan out their unsatisfied longings in vapid admiration of sentimental nonsense, whether it be in poetry, music, or painting, and find out something "quite too lovely" in a line, a strain, or a daub that no sensible man would care to hear or see again. The great source of disease, said Dr. Reynolds, against which preventive medicine has shown its strongest powers, and with which it now wages war the most vigorously and incessantly, is the introduction of noxious matter, either with food, by the air we breathe, or by direct inoculation. Further on in his address he added that in this part of the nineteenth century we come into contact with excess of work—mental, moral, and physical—on almost every hand. Mental work is not excessive if the appetite be good and the sleep sound.

On the motion of Lord Basing, seconded by Dr. Carpenter, a vote of thanks was given to Dr. Reynolds.

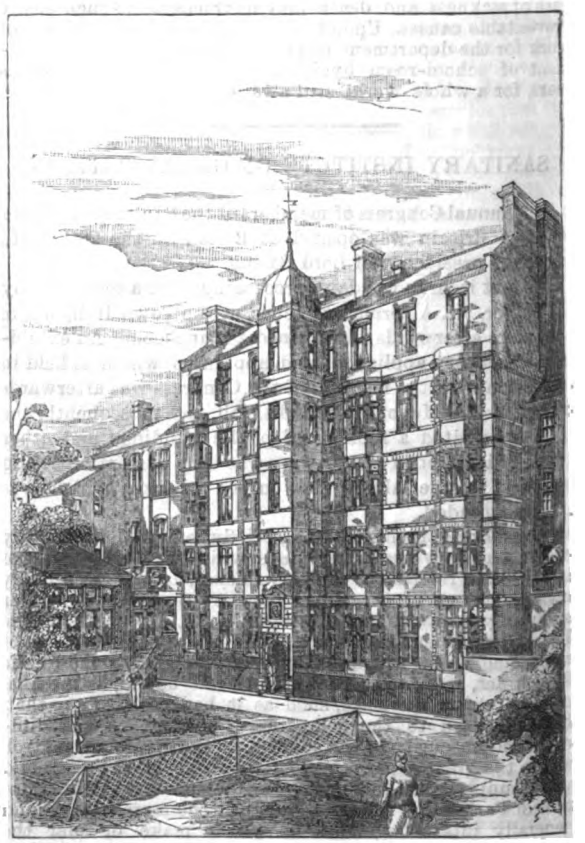
Mr. Sergeant, medical officer of health for Bolton, followed with an address describing a decade of sanitary improvement in the town, showing a decreased death-rate, the erection of a fever hospital, the establishment of disinfection work and sewage works; and he specially dwelt on the Corporation powers for the compulsory notification of disease, of which he spoke highly. In the case of small-pox, the disease, he said, could be kept in almost perfect check, and scarlet fever restrained, and there was less danger of the disease being spread by children attending school.—

Digitized by Google

Mr. North, medical officer of health (York), bore testimony to the benefit which had accrued to York from the adoption of compulsory notification of disease. Without it they could not have discovered the source of a grave outbreak of typhoid fever, due to infected milk.—Professor Corfield also supported the system, and pointed out the fact that the death-rate from zymotic diseases in Bolton had fallen from 20·2 to 16·2. He advocated the closing of schools to prevent the spread of measles.—Mr. E. C. Robins and Dr. Carpenter spoke in favour of the water-carriage system in preference to the pail system for the removal of sewage, and the latter added that for thirty years he had advocated the notification of infectious diseases; but he contended that the notification should be made by the medical man to the occupier, and not to the medical officer direct.—Dr. Tatham (Salford) having added his testimony to the advantages of the notification of diseases, Dr. Macfie (Bolton), whilst admitting that the majority of Bolton practitioners differed from him, agreed with Dr. Carpenter, and held that though the law was enforced as it was, in Bolton cases were kept secret.—Mr. Sergeant having replied, a vote of thanks was passed to him.

Dr. Livy, J.P., Bolton, read a paper on the "History and Progress of Public Health." Dr. Alfred Carpenter contributed one on "Our Pioneers," referring especially to Dr. Parkes and Dr. Farr; and Mr. D. M'Keown (Manchester) one on the "Prevention of Blindness," which recommended a Governmental instruction of people by cards, distributed by the registration officers, giving advice as to the treatment of infants' eyes.—After the reading of the latter paper the Congress rose.

In the evening a conversazione was given in the Albert Hall by the Mayor, Alderman Fletcher, to which 750 invitations were issued.



THE CONGRESS OF GERMAN PHYSICIANS AND NATURALISTS AT WIESBADEN.

THE most interesting feature of this—the sixtieth—assemblage of the medical and physical *savants* of Germany is the Exhibition of Scientific Apparatus in the great hall of the Government Buildings. At 10 A.M. on the 15th inst., Dr. Ludwig Dreyfuss delivered the opening address on the aim and character of the Exhibition. In convenient space and in comprehensive *ensemble* the collection places on view the achievements of the last few years in the apparatus and appliances for research in physics and in natural history, for instruction in these departments, and for the tuition and practice of the healing art in its great branches of medicine, surgery, and public hygiene. It enables the members of the Congress to become practically cognisant of the newest and highest improvements in the working tools of their several specialties, to compare them with those hitherto in use, and to suggest still further modifications in the direction of increased efficiency. A hearty vote of thanks to the liberal exhibitors concluded the address, coupled with a special compliment to the representatives of the Berlin committee, Geheimrath Bardeleben and Dr. Lassar, for their effective co-operation. The Exhibition was thereafter consigned to the Congress, in whose behalf Professor Fresenius expressed the gratitude of the members, and dwelt on the signal utility of the collection as an earnest of still higher achievements in the same field. No fewer than 491 scientific instrument makers have contributed the choicest specimens of their handiwork, which occupy several spacious rooms. Of the members already assembled there are over 200, and an elegantly got up publication in connexion with the Congress contains two treatises of more than local interest: the "Water Supply of Wiesbaden," scientifically handled by the director of the works and the "Canalisation of Wiesbaden," by the engineer, Herr Brix—also comprehensive and instructive. Chemical Analysis is represented by Professor Fresenius, and Bacteriology by Dr. F. Hueppe.

INDIAN LADY DOCTORS AND THEIR FEES.—Complaints are finding vent in India on the question of the amount of fees demanded by the lady practitioners amongst the native population. Says the *Lahore Tribune*: "People in India are willing to pay two rupees for a visit, but cannot give more, except on the occasion of a first call, and the natives think that, as Lady Dufferin's Institute is aided by subscriptions, the doctresses ought to be moderate."

THE NEW RESIDENTIAL COLLEGE AND SCHOOL BUILDING AT THE MIDDLESEX HOSPITAL.

ON a site of ground, having a frontage in Cleveland-street on the one side and overlooking the garden at the rear of the hospital on the other, has been erected this year a building designed and constructed expressly for the purpose of affording to medical students a comfortable college home in close proximity to their work. The garden frontage, which forms the principal elevation, consists of a red brick building, six storeys in height and relieved by bay windows, constructed of buff-coloured terra-cotta, giving the building a very bright and cheerful appearance. The style of architecture is an adaptation of late Elizabethan mullioned and transomed windows, with classic mouldings. The College is calculated to contain about thirty students, each of whom is provided with an apartment shut off from the main corridor by double doors. This apartment comprises a sitting

room, well lighted and comfortably furnished; the sleeping accommodation is in the same room, divided off by a curtain and having a separate window. In addition, there is on the ground floor a fine large dining hall, a large common reading and recreation room, and a good-sized study.

The sanitary arrangements are all contained in a tower running the whole height of the building, thus being separated from the main block by a passage freely ventilated on either side. Students residing in the College will pay so much rent for their rooms, and be provided with meals in hall at a tariff which is very moderate, or they can arrange for terms, including board. A Warden will reside in the College, and one of his chief duties will be to assist the students in their work in the evenings. The domestic arrangements are under the management of a resident steward.

The College has been erected by the friends and supporters of the hospital and medical school, and we heartily wish the scheme all the success which its enterprise deserves. Every effort appears to us to have been made to give the student

Digitized by Google

a healthy home, with all reasonable comfort; and the many advantages which he must possess in residing practically on the hospital premises must be obvious to everyone. He will be free to enjoy the companionship of his fellows, or, if he desires, he can completely shut himself up in the quiet and privacy of his own room; whilst his proximity to the hospital will afford him opportunities of visiting the wards, and of gaining experience from the emergency practice, which those living at a distance away cannot possibly enjoy. The rules and regulations of the College, we are glad to find, are such as to secure the social advantages of a college life without irksome restraint.

Adjoining the College a very important and extensive addition has been made to the medical school buildings. The new building consists of four storeys. In the basement are a large luncheon room and excellent lavatories; on the ground floor is a students' reading room, a lecture theatre, the dean's room, and a cloak room. From the vestibule a staircase leads on the first floor to a spacious, lofty, and well-proportioned library, which occupies nearly the entire area of the new buildings. Above this the whole of the upper floor is devoted to a physiological and pathological laboratory and class room; this room is lighted from both sides by wide lofty windows, and is specially constructed and fitted up with a view to microscopical work. The only approach to the school buildings has hitherto been through the hospital and across the garden, but in future the entrance to the school will be in Cleveland-street.

The room hitherto used as a physiological laboratory will now be the Practical Surgery Class Room, and the old library will contain the Materia Medica Museum, and serve as an additional class room.

The whole of these buildings have been erected by Messrs. Holland and Hannen, from designs prepared by Mr. Keith D. Young, architect to the hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5626 births and 3186 deaths were registered during the week ending September 17th. The annual rate of mortality in these towns, which had steadily declined in the preceding five weeks from 23·7 to 18·8, further fell last week to 18·0. During the first eleven weeks of the current quarter the death-rate in these towns averaged 21·1 per 1000, and corresponded with the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·0 in Derby, 15·6 in Huddersfield, 15·7 in London, and 16·8 in Bristol. The rates in the other towns ranged upwards to 24·4 in Halifax, 25·8 in Manchester, 26·0 in Salford, and 27·0 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding seven weeks from 1301 to 768, further fell last week to 624; they included 294 from diarrhœa, 116 from scarlet fever, 84 from whooping-cough, 48 from "fever" (principally enteric), 37 from diphtheria, 34 from measles, and 11 from small-pox. These zymotic diseases caused the lowest death-rates last week in Huddersfield and Leicester, and the highest rates in Preston, Salford, and Bolton. The greatest mortality from diarrhœa was recorded in Wolverhampton, Salford, and Bolton; from scarlet fever in London, Salford, Oldham, Bristol, Bolton, Manchester, Birkenhead, and Preston; from measles in Blackburn, and from "fever" in Salford. Of the 37 deaths from diphtheria in the twenty-eight towns, 20 occurred in London, 3 in Manchester, 2 in Brighton, 2 in Portsmouth, 2 in Norwich, 2 in Oldham, and 2 in Leeds. Small-pox caused 9 deaths in Sheffield 1 in Liverpool, and 1 in Cardiff, but not one in Greater London or in any of the twenty-four other large towns. Only 5 cases of small-pox were under treatment on Saturday last in the Metropolitan Asylums Board hospitals receiving cases of this disease; while the number of cases of scarlet fever in these hospitals had increased to 1035. The deaths referred to diseases of the respiratory organs in London, which had been 169 and 160 in the preceding two weeks, further fell last week to 142, and were 42 below the corrected average. The causes of 68, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Newcastle-upon-Tyne, Portsmouth, and in nine other smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Sheffield, Oldham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·5 and 19·4 per 1000 in the preceding two weeks, declined again to 18·7 in the week ending September 17th; this rate was 0·7 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·0 and 13·7 in Aberdeen and Greenock, to 25·2 in Leith and 26·5 in Paisley. The 467 deaths in the eight towns last week showed a decline of 17 from the number in the previous week, and included 55 which were referred to diarrhœa, 19 to whooping-cough, 17 to scarlet fever, 11 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 1 to small-pox, and not one to measles; in all, 106 deaths resulted from these principal zymotic diseases, against 102 and 112 in the preceding two weeks. These 106 deaths were equal to an annual rate of 4·2 per 1000, which exceeded by 0·7 the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 53, 39, and 45 in the previous three weeks, further rose last week to 55, of which 13 occurred in Glasgow, 10 in Dundee, 10 in Leith, and 9 in Edinburgh. The 19 deaths from whooping-cough showed a marked decline from the numbers in recent weeks, and included 4 in Glasgow, 3 in Edinburgh, 3 in Greenock, and 3 in Leith. The 17 fatal cases of scarlet fever, on the other hand, exceeded the number in the previous week by 6; 6 occurred in Glasgow, 6 in Dundee, and 2 in Edinburgh. The 11 deaths referred to "fever" corresponded with the number in the previous week, and included 5 in Glasgow and 4 in Paisley. Two of the three fatal cases of diphtheria were returned in Dundee; and the death classed to small-pox was said to be a fatal case of chicken-pox in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 73, 71, and 66 in the preceding three weeks, rose last week to 77, and exceeded the number returned in the corresponding week of last year by 12. The causes of 68, or nearly 15 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 37·5 and 27·9 per 1000 in the preceding two weeks, rose again to 34·3 in the week ending September 17th. During the first eleven weeks of the current quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 20·5 in London and 18·4 in Edinburgh. The 232 deaths in Dublin last week showed an increase of 43 upon the number returned in the preceding week; they included 35 which were referred to diarrhœa, 8 to measles, 2 to "fever" (typhus, enteric, or simple), 3 to whooping-cough, 2 to scarlet fever, 2 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 48, 65, and 77 in the preceding three weeks, declined again last week to 52; they were equal to an annual rate of 7·7 per 1000, the rate from the same diseases being but 3·0 in London and in Edinburgh. The fatal cases of diarrhœa, which had been 30, 31, and 36 in the previous three weeks, were last week 35. The deaths from measles, "fever," and scarlet fever showed a considerable decline from the numbers in recent weeks. The 2 deaths referred to diphtheria were the first recorded in the city since the beginning of August. The deaths of infants considerably exceeded the numbers registered in the previous week. Six inquest cases and 4 deaths from violence were registered; and 75, or nearly one-third, of the deaths occurred in public institutions. The causes of 29, or nearly 13 per cent., of the deaths registered during the week were not certified.

ABERDEEN ROYAL INFIRMARY.—A fresh appeal for subscriptions towards carrying out the scheme of reconstruction or extension of the infirmary has been issued by the House Committee. By the former appeal, for the raising of the sum of £30,000, £24,886 has been realised.

"Audi alteram partem."

"RAPID DILATATION OF THE CERVIX UTERI."

To the Editors of THE LANCET.

SIRS,—Having read with much interest in THE LANCET of Sept. 10th a paper by Dr. Lewers advocating "rapid dilatation of the cervix uteri," I wish to add my testimony in confirmation of his belief in the safety and advantages of the method, and of its superiority over the older one of dilatation by tents. For many years I have adopted the method, and with increasing frequency and confidence, in cases of uterine hæmorrhage, menorrhagia, and dysmenorrhœa, and more recently, combined with scraping, in cases of erosion of the os and cervix uteri, and have been collecting data for a paper which I hope ere long to publish.

The satisfactory use of rapid dilatation is very much a question of details, and those which I have adopted are very much on the same lines with those described by Dr. Lewers, and are—(1) ether; (2) lithotomy position; (3) fixation of os uteri by two pairs of vulsellum forceps of special form, with short teeth and catch; (4) dilatation by Dr. Matthews Duncan's sounds, followed, if more dilatation be necessary, by Hegar's sounds; (5) thorough application to the uterine cavity of pure melted carbolic acid, due precautions being taken against scalding the vagina; and (6) introduction into the vagina of special iodoform pessaries, which dissolve slowly, instead of melting rapidly, the formula of which was given to me by Dr. Champneys.

I am, Sirs, yours faithfully,

Leeds, Sept. 1887. T. PRIDGIN TEALE.

PAIN AND ITS INTERPRETATION.

To the Editors of THE LANCET.

SIRS,—In response to Mr. Gillies' last letter, I may venture to suggest that the subjects of "pleasure" and "pain" might well be considered together. The two stand out in bold contrast, not only as to the nature of the sensation, but as regards the bodily state which they accompany. For all will agree that, in the main, pleasure signifies health, and pain, disease. The pleasures and pains I am more particularly referring to are those of the grosser kind—such as the pleasures of eating and bodily health, and the pains of physical hurt. Let us suppose the vital changes to be proceeding healthily; myriads of impulses pass up from the skin, viscera, and muscles, and, striking upon the sensorium, yield that vague and ill-defined, but none the less glorious, feeling of well-being. How very little will disturb all this. An undigested meal, the fine sting of a gnat, nay, even "a wandering hair," may soon cast us from our high pinnacle of pleasure, plunging us into an abyss of utter misery.

Now, the natural tendency of pleasure is to cause us to persist in the healthful act which causes it, and of pain to desist from the hurtful cause. The two therefore are strictly utilitarian. The mode in which they effect these good results is interesting. It is partly involuntary and partly voluntary. Concerning the first, Bain's law of self-conservation runs thus: "States of pleasure are concomitant with an increase, and states of pain with an abatement, of some or all of the vital functions." A pleasurable feeling therefore tends, by a hurrying on of the vital processes, to a continuance of the act which causes it, as when a child sucking at the breast is led by the relish of the milk to apply itself with increased vigour to the securing of it; while, on the other hand, a painful feeling, by depressing the vital processes, leads to a discontinuance of the pain-producing act, such as the chewing of an unpalatable food. In such cases pleasure and pain work out the desired result more or less automatically. As the will grows, however, the pursuit of pleasure and the avoidance of pain become more and more a matter of volition. But it is not only the grosser organic pains which urge us to action; there are pleasures and pains of a far more refined order—such as the pleasures of fine art, poetry, affection, learning; and the pains of anger, disappointment, dread or remorse. Thus, there are two opposing series of mental forces—the one urging us *to do*, the other bidding us *not do*. It is, in fact, these pleasures and pains, either actual or remembered, which constitute our motives to action. How far *they* manage *us*, or *we them* is a matter of speculation, but I imagine they have it a good deal their own way.

I say pain and pleasure are utilitarian, for the one leads to the avoidance of harm and the other to the pursuit of good. What should we do without them? If pain did not attend evil, we should for ever be rushing into destruction; and did pleasure not accompany good, we should never seek after it, unless indirectly by the avoidance of harm. Let us, for instance, assume an individual incapable alike of the pangs of hunger and the delights of eating—would he not be rather apt to neglect this very necessary process? In short, without the capacity for pleasure and pain there would be no impulse to action one way or the other. Hence, the two have been necessary factors in the evolution of mind. The existence of an intellectual being having no capacity for pleasure and pain is conceivable, but the evolution of such a being quite inconceivable. Possibly a higher complex reflex organism might evolve, but one endowed with intellect *never*. Indeed, as regards the existence of such reflex organisms, I have never been able to shake off the lingering belief that many of the invertebrates are devoid of even the crudest sensation. Although the facts, therefore, plainly prove that pleasure and pain have both a tremendous purpose, yet a writer in your columns gravely affirms of one of them that it is purposeless.

Concerning the evolution of pleasure and pain, how has it so happily come about that pleasure attends healthful action and pain the reverse? Let us assume the existence of a crude sense in a lowly organism. At this early stage there is no differentiation into a sense of pleasure and pain, the mental world being, as Spencer might say, *homogeneous*: but soon the homogeneous passes into the heterogeneous—there is a dim discernment of pleasure and pain—for I imagine this differentiation must have occurred before the differentiation into the special senses. Now I see no reason why pleasure should have originated on the side of health, and pain on that of disease. It might, for aught we know, have been the reverse. Be this as it may, the principle of natural selection would very soon couple health with pleasure and a disturbance of it with pain, seeing that the opposite state of things would lead to extinction. Undoubtedly pleasures have thus grown. Take a single instance—the pleasures of love,—and see how marvellously they are adapted to the propagation of the race. It is manifest that natural selection has secured this, but is this process the sole factor in the evolution of pleasure and pain? Herbert Spencer, in the second volume of his Biology, points out that natural selection cannot account for a large part of organic evolution; for instance, the æsthetic sense cannot have developed thus. It has grown by cultivation through many generations—that is, by *use*; and, indeed, Darwin, in his later editions, acknowledged that he had not attributed sufficient importance to the "use and disuse of parts." There can be little doubt that not only the æsthetic pleasure, but pleasure in general has thus been very largely added to. The capacity for pain, however, cannot well be strengthened by *cultivation*; but I think we may lay it down as a rule, be the explanation what it may, that individuals who have the greatest capacity for pleasure—I ought perhaps to say the higher pleasures, such as the pleasures of poetry or music—are, at the same time, most sensitive to pain. Certainly, different individuals feel pain in different degrees, and this raises the interesting question: Have we any right to say that some can bear pain better than others, for how do we know that the seemingly better toleration of the pain may not be due to a lesser feeling of it? When pain attains a certain pitch, I imagine that it is unbearable for anyone and everyone. If a man by great force of will brings himself to bear what would be to others unbearable, is it not rather because by his very effort the pain is diminished? We have no right to say that the Fakir, who plunges a hook into his flesh and thereby suspends himself to the branch of a tree while a fire burns beneath, can bear pain better than others. I have heard a man solemnly avow that he derived the keenest pleasure from the operation of the dentist, such as the scraping and filing of teeth. If one did not know this little weakness of his,

Digitized by Google

one might fancy that he displayed the most heroic courage by the calmness of his demeanour while under the dentist's hands.

One word more. I have said that pleasure and pain are utilitarian; but just as pain has its imperfections, so has pleasure, but of these I will say nothing.

I am, Sirs, yours faithfully,

Guilford-street, Sept. 19th, 1887. HARRY CAMPBELL, M.D.

To the Editors of THE LANCET.

SIRS,—As a firm believer in the theory of evolution, I am not likely to dispute the main propositions of Drs. Collins and Campbell in recent numbers of THE LANCET. Still, it appears to me that some aspects of the problem of pain which are worthy of attention have been forgotten in the discussion. Pain, like all disease, may be regarded as a consequence of a failure of correspondence with the conditions of life. Whether the balance is restored by changes in the conditions or in the organism itself depends on many circumstances, and need not now be discussed. All early symptoms are in a sense warnings against later morbid states due to the same causes; and in many cases pain acts as a very effective warning. Where it occurs too late to warn the individual it still has a powerful influence for good upon the community. The web of modern civilisation is becoming so complex that the misfortune of one is more and more the concern of all, and society, as a whole, has to bear many of the penalties of individual blundering or transgression. This tends to increase the sympathy of the whole for the sufferers, and in a community where intelligence is increasing provides a powerful motive for the investigation of disease. Many diseases are due to conditions only removable by united action, and it is therefore a distinct advantage to widen the basis of retribution. Probably far less attention would have been paid to the physiology of parturition had the process been a painless one, although in this instance there are several other reasons for believing the pain to be useful. It is the painfulness quite as much as the fatal nature of cancer and hydrophobia which has excited attention and brought us to the threshold of new methods of treatment—at all events as respects one of these dread scourges of humanity. In conclusion, it appears to me that pain must be regarded as only one of many evidences that there is something amiss—something to be rectified; and, looked at in this light, it will seldom fail to be indirectly useful. Of the purely moral benefits of pain I will say nothing, but merely add that if pain be supposed to sweeten the character, so will its relief.

I am, Sirs, yours faithfully,

F. RUFFNACHT WALTERS, M.D. Lond.

Finsbury-circus, Sept. 17th, 1887.

To the Editors of THE LANCET.

SIRS,—Will you allow me to make a few remarks—the last as far as I am concerned—on the subject of pain and its interpretation?

I think the bulk of your readers will agree with me that Mr. Gillies has failed to make any converts to his creed. At any rate, he has fought his battle single-handed, for no champion—unless we except Dr. Hayman—has come forward in support of his views. Mr. Gillies, without denying the truths of evolution, "is of the same opinion still." What he cannot accept is that "pain stands out simply as an evidence of evolution." What *we* cannot accept is that "pain has some other and higher purpose than that." This is very much the position from which we started! Mr. Gillies says: "It is with the meaning, the motive of pain, that I am concerned, not with the process of its evolution." Surely the one should be dependent on the other. We do not admit any special meaning or motive. We see in pain the expression of a high degree of sensibility in the nervous system; and we believe the nervous system has attained its present high degree of sensibility by reason of long and steady development—evolution, in fact. But Mr. Gillies will not concern himself with evolution. He is content to take pain as he finds it, where evolution has brought it, and seek a *motive* in it without considering the nature of its existence—its *raison d'être*—at all. Is it not manifestly unlikely, to say the least, that a nervous system sufficiently developed to receive and convey a high measure of pleasurable sensation should be incapable, under other conditions, of also receiving and conveying an equally high measure of *all* sensations, pleasurable or otherwise? "Sauce for goose is sauce for gander." I can thus see a reason for the existence of pain, but no motive or purpose.

I am, Sirs, yours truly,

A. ST. CLAIR BUXTON, F.R.C.S.

Orchard-street, Portman-square, W., Sept. 20th, 1887.

PROTECTIVE POWER OF VACCINATION.

To the Editors of THE LANCET.

SIRS,—In your number of the 10th inst., Dr. Wm. Squire says that the experience of our late epidemics of small-pox suffices to upset the theories that vaccination performed within four days of the infection of small-pox would be in time to prevent the development of the latter, and that if vaccination could proceed to the stage of areola it would be in time. Marson stated it as his opinion, founded I presume on experience, however it was to be accounted for, that, "suppose an unvaccinated person to inhale the germ of variola on Monday, if he be vaccinated as late as the following Wednesday the vaccination will be in time to prevent small-pox being developed; if it be put off until Thursday, the small-pox will appear, but it will be modified; if the vaccination be delayed until Friday, it will be of no use, it will not have had time to reach the stage of areola, the index of safety, before the illness of small-pox begins." Again, so late as July 3rd, 1886, we read in THE LANCET: "A Russian medical student (M. Gubert), by repeating the vaccination on three successive days, was able to produce matured vesicles in four or five days. This rapid saturation of the organism with the vaccine virus enabled M. Gubert to arrest the development of the disease in twenty-seven persons in whom, he states, he was quite certain that the small-pox was incubating, while in twelve others the disease was so modified as to be considered only varioloid. All the experiments were carried out with calf lymph." May I ask, Where is the record of the experience to which Dr. Squire refers to be found?

I am, Sirs, yours faithfully,

HUGH THOMSON, M.D.

Lansdowne-crescent, Glasgow, Sept. 19th, 1887.

SCARLATINA OR SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—A very widely spread belief in the minds of the working classes that scarlatina allows of the above classification is, I feel convinced, a powerful factor in the spread of this dangerous disease. Few who have treated the affection amongst the class I refer to have failed to observe the effect produced by the word chosen. If without thought the medical man pronounces the patient to have "scarlatina," a contented and relieved expression of countenance is at once observed, and is, in almost nine cases out of ten, followed by the remark, "I was afraid it was 'the fever,'" meaning scarlet fever. If the latter word is used a very different effect is produced. The full danger appears to be realised, but the diagnosis is doubted if the patient does not appear very ill. I feel sure that much harm results from this state of ignorance amongst the majority, and does much to render useless the efforts made to check this disease during an outbreak. "Scarlatina" is looked on as so trivial an affection that precautions of all kinds are too often ignored. Children are apt to be sent to school, allowed to mix with their brothers and sisters, and others permitted to frequent the infected houses. It is simply useless for the individual medical man to try to explain that there is no difference between scarlatina and scarlet fever. I believe, however, that much good may be obtained if this fact were stated on the notices posted throughout the districts inhabited by the class who entertain the dangerous views I describe.

I am, Sirs, yours faithfully,

Battersea Park, Sept. 19th, 1887. W. CARY JEFFRIES.

AT an inquest held last week at Bedworth, North Warwickshire, on the body of Charles Herbert Ford, L.R.C.S.I., who died after taking three drachms of a solution of morphia, representing eighteen grains of the drug, the jury found that the deceased destroyed himself while of unsound mind.

LIVERPOOL.

(From our own Correspondent.)

THE GYMNASIUM.

THE importance of due attention being paid to physical development in children of both sexes, as well as in young men and women in whom it has been previously neglected, is now generally admitted. It follows, therefore, that one or more well-organised gymnasia are becoming necessary features in every large community. Liverpool has long recognised this fact. More than thirty years ago the late M. Hugenin had his gymnasium near the Exchange, conveniently situated for men of business who could slip away from desk and counter for a half-hour's gymnastics, the value of which to men whose daily avocations involved stooping over desks and confinement in close offices could not be over-estimated. Later on this old gymnasium was found quite inadequate to meet the accommodation required, and by the energy of the late Mr. Hulley, aided by numerous influential friends, the present gymnasium was erected. It is now under the superintendence of Mr. Alexander, under whose able management it has been very successful. He has recently published a small work entitled "Modern Gymnastic Exercises (Elementary)," which will be found well worthy of perusal. As he truly observes in it, "Making poor stunted forms strong healthy physiques, discontented men bright and happy beings, is good service indeed." The most valuable exercises of all are the classes of dumb-bells, Indian clubs, and bar-bells, with musical accompaniments. These bring into play all the muscles of the body, and change puny delicate lads into strong active young men.

WORK DONE BY THE SCAVENGING STAFF.

Some idea of the enormous work thrown upon the local scavenging staff may be judged by the following details. In an average year 7000 middens and a quarter of a million dry ashpits are emptied. Nearly 18,000 loads of refuse collected by citizens, and more than 100,000 loads of refuse swept up by the scavengers from the streets, courts, and passages of the city, are removed by "bell-cart."

EMPTYING ASHPITS AND DIARRHŒA.

Although in Liverpool, as in other large cities, modern progress has changed most of the old "privies" into water-closets, dry ashpits are still required for the purposes of receiving animal or vegetable refuse. There is no doubt that burning is the best mode of disposing of the latter, but unfortunately the average kitchen ranges, both ancient and modern, are not constructed with this view. It becomes necessary, therefore, that these dry ashpits containing vegetable refuse should be emptied at reasonably frequent intervals, the alternative meaning an obvious source of danger in the proximity to any dwelling of any decaying animal or vegetable matter. At the same time, frequent removal in hot weather is to be deprecated, especially if there be reason to believe that this is a cause of diarrhœa as has been suggested. The subject is under consideration.

NARROW ESCAPE OF FIREMEN.

The superintendent of the local fire brigade, with one inspector and four firemen, had a narrow escape at a fire which occurred on board the steamer *Scholer*, while in one of the docks. When the men descended into the fore-peak of the steamer, where it was believed the fire existed, they were at once overcome by noxious gases or chemical fumes, supposed to be caused by the combustion of some portion of the cargo, which consisted of cotton and other goods. They were hauled up in an unconscious condition, but speedily recovered by proper treatment, except one fireman, who had to be removed to the Royal Southern Hospital, where he soon recovered. Superintendent McWilliam, who has had many years' experience of fires, and is accustomed to the densest smoke, stated that he had never experienced anything so peculiarly overpowering on any previous occasion.

DEATHS FROM HYDROPHOBIA.

An inquest has been held by the borough coroner on the body of a boy eight years of age, who died on the 17th inst. in the Royal Infirmary from hydrophobia. The case was seen by Drs. Glynn and Davidson as well as Dr. Hugh R. Jones, the house physician, who gave evidence at the inquest. It appears from the evidence that the boy was bitten on July 30th by a dog at the back of the house occupied by the deceased's father. The dog was a sheep dog, and the boy's hand was bitten through. His mother stated that it bled profusely, and that she took him at once to a surgeon, who dressed the hand. The boy apparently recovered from the injury, but on the 13th inst., while walking with his father, he complained of pain in the affected hand, and that it went right up his arm. As he became delirious that evening, a doctor was called, and he was taken to the Royal Infirmary, where he remained till his death. All the symptoms of hydrophobia were well marked, and the post-mortem examination confirmed this. The same dog bit a lady, a Mrs. Atkinson, who most courageously went to the rescue of the boy; she has undergone the Pasteur treatment, and so far successfully.

A second victim to the same dog above alluded to has just died. This was a boy nine years old, the son of a widow residing in Wavertree, a township distant three miles from Liverpool. This boy was bitten on July 30th in the calf of the left leg, five distinct marks being subsequently found. He was at once taken to a chemist's, where the wounds were cauterised, the bites healing very rapidly. On the 17th inst. he first complained of feeling unwell, wished to lie in bed, and refused liquids. On the next day (Sunday) he was much worse, and on Monday Dr. Wearing of Wavertree was called in. The little fellow became delirious, and in the afternoon of the 20th he died. A large number of wandering dogs are annually seized by the police, and if not claimed or sold are destroyed, but, in spite of this, there are still many loose dogs in the streets.

Liverpool, Sept. 21st.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

HEALTH OF SUNDERLAND.

MR. A. E. HARRIS, the medical officer for the borough, has issued his report on the Sanitary Condition of Sunderland for 1886. The document is a long one, too much so to analyse in these notes; but upon the whole it is most interesting and instructive, as showing the result of vigorous sanitary measures upon the health of the people of Sunderland: indeed it is not too much to say that since THE LANCET's report in 1884 a sanitary revolution has been effected in the Wearside borough. The death-rate for 1886 was 19·4 per 1000, the nearest approach to which was 20·8 in 1880. The average death-rate for the previous ten years was 23·5. The decreased mortality, Mr. Harris shows, is not confined to any one group of ages, but is general to all groups except one—viz., those between fifteen and twenty-five years of age. The greatest decrease occurs among children under five years of age, of which there is a falling off of 390 deaths. Mr. Harris very clearly and forcibly shows that the age distribution of Sunderland tends to a low mortality. Its configuration is favourable, its water supply unexcelled, its sewerage system good, and finally, he says, the Health Committee have done and are still anxious to do all in their power to promote the health of the borough, so that, as a result, the decline in miasmatic or "filth" diseases is the most noticeable and most gratifying feature in Mr. Harris's returns. With regard to the care exercised as to food inspection, he mentions that no less than 77,000 herrings were seized as unsound. He is, however, far from being fully satisfied, but looks forwards to a reduction of the annual death-rate to about 16 per 1000, which he thinks should be about the normal figures. Be this as it may, he is to be congratulated on the success achieved so far under circumstances which might have led a less resolute medical officer of health to despair.

DRUNK OR DYING.

An unfortunate mistake occurred at Middlesborough last week, when an elderly and well-dressed female became insensible in a tram-car. The conductor removed her and set her on a door step, from which she was afterwards removed in a barrow to the police station. Dr. Longbotham, on seeing her, very properly ordered her removal to the workhouse, where she remained unconscious for a few hours, and died.

SCARLET FEVER IN NEWCASTLE.

The return of infectious diseases notified by practitioners in Newcastle to the medical officer of health during the fortnight ending Sept. 10th shows the unusually large total of 116 cases. No district appears to be free, but it is worst at the extremes of the city east and west. Enteric fever is also shown to be rife. The heavy rains which have set in here since the commencement of September have caused a marked fall in the previously high temperature.

TYNEMOUTH WATER SUPPLY.

Many will be pleased to see that the Town Council of Tynemouth are about to take steps to bring a supply of proper drinking water to the place. The defective quality of the water at Tynemouth has been the means of preventing this favourite health resort from receiving anything like the number of visitors who would otherwise gladly go there, for the convenience of Tynemouth to our great northern towns and its natural attractiveness give it a position not easily surpassed.

A DACOIT'S HAIR.

One of the Royal Welsh Fusiliers, who returned to Newcastle the other day from Burmah, where he has been engaged with the Dacoits, has brought home a curiosity in the shape of the long hair cut from one of the robbers who was shot on the river Moo. It is jet black, and its extreme length is sixty-seven inches.

Newcastle-on-Tyne, Sept. 21st.

EDINBURGH.

(From our Correspondent.)

POST-GRADUATE COURSES.

THE second session of Post-Graduate Lectures will commence on Monday, Sept. 26th, and will be continued for three weeks. Since the inauguration of these lectures last year, there has been a considerable development both in the subjects included and in the amount of instruction to be given in the various branches. The unexpected success with which last year's effort was attended has encouraged the committee to make much more extensive preparation for the present season. Every branch of medical education is to be represented. In Dental Diseases, six demonstrations showing most recent advances in the practice of dentistry have been arranged by the lecturers of the Edinburgh Dental School. Diseases of Children are to be treated in four clinical demonstrations at the Sick Children's Hospital by the physicians to that institution. Obstetrics and Gynæcology are to be treated by Professor Simpson, Drs. Croom, Hart, and Barbour in a series of daily demonstrations at the Royal Infirmary. The Throat and Ear are to be dealt with by Dr. Duncanson, Dr. McBride, and Dr. Mackenzie Johnston, in a series of special lectures and clinical demonstrations. Dr. Argyll Robertson, Mr. Berry, and Mr. George Mackay will hold courses of clinical instruction in Eye Diseases. Dermatology and Syphilis are to be treated by Dr. Allan Jamieson and Dr. MacGillivray respectively, both theoretically and clinically. At the Royal Infirmary, the medical out-patient department is to be largely put into requisition, the assistant physicians, Drs. Smart, James, and Byrom Bramwell, having each a special series of clinical demonstrations, in addition to lectures on important points in practical medicine. General Medical Diseases have eight lectures allotted to them. These will be delivered in the infirmary by the physicians and the University Professors of Clinical Medicine, and they will be illustrated by clinical cases at present in the hospital. In the Surgical department a similar course of five lectures on General Surgical Diseases will be conducted by the surgeons to the infirmary and the University Professors of Surgery and Clinical Surgery. Mr. Cathcart, assistant surgeon to the infirmary, is to contribute a course of demonstrations on Artificial Limbs and on the taking of casts. In Pathology an extensive course of instruction in Practical Bacteriology is arranged under the charge of Drs. Woodhead and Edington. Mr. Bruce will give seven demonstrations on the Pathology of the Brain and Spinal Cord, and Mr. Macdonald Brown two demonstrations on Bone in its relations to Disease. Mental Diseases are to be dealt with by Drs. Clouston and Batty Tuke; and Medical Police by Dr. Littlejohn, medical officer of health for the City of Edinburgh. Regional Anatomy is to be extensively dealt with by Drs. Symington and Macdonald Brown, whose courses of demonstrations will cover all the more important regions of the body. Dr. Murdoch Brown will demonstrate microscopically the Parasites of Man and Urinary Deposits. Dr. Craig is to give a series of lectures on New Remedies and Dr. Felkin on Climatology. Vaccination will be taught clinically by Drs. Husband and Buist. For those attending the course, each day will be very fully occupied if they attempt to avail themselves of even a part of the curriculum; it is now sufficiently expanded to allow of a considerable amount of specialisation on their part, since each subject is in itself dealt with in a variety of ways, and so extensively as to convey an advanced knowledge of its present aspect. Tickets for the whole course can be obtained at a cost of two guineas from either of the secretaries, Dr. Claud Muirhead and Professor Chiene, Charlotte-square, Edinburgh.

Edinburgh, Sept. 20th.

DUBLIN.

(From our own Correspondent.)

QUEEN'S COLLEGE, GALWAY.

THE President, in his report for the past session, states that he feels satisfaction in the reflection that the College can justly claim to have given an impulse to educational progress throughout the country, and more especially to have conferred substantial benefits on the youth of a remote and outlying province. The change in the position and relations of the Queen's Colleges has in nowise affected the duties and the tasks of the teaching body of the College. While the collegiate discipline of lectures and instruction in common is not relaxed, the College has recognised facts as it has found them, and has adapted its curriculum to meet the rules and requirements of the Royal University of Ireland. And it may be hoped, the President adds, that the thoroughness of the intellectual training which the collegiate system ensures will exhibit results that will ultimately secure for it even higher appreciation, and enable it to keep pace with the growing educational demands of the country and the time. The students in attendance during the session 1886-87 numbered 103, of whom 45 were in the Faculty of Medicine, the total showing an increase of nine as compared with the previous return. The library and museums are in a satisfactory condition, while large additions have been made to the Natural History Museum, which is now in a perfect state of efficiency for teaching purposes. The apparatus for the illustration of the principles of natural philosophy, and the collections specially devoted to the studies of the medical profession, are worthy of particular notice. The rapid development of medical science, especially in the biological department, demands constant enlargement and improvement of the scientific apparatus necessary for the purposes of instruction; and it is satisfactory to learn that the provisions for the study of practical physiology and histology are commensurate with the growth and importance of these sciences.

ROYAL UNIVERSITY OF IRELAND.

Dr. Knight, Lecturer on the Practice of Medicine in the Ledwich School of Medicine, will be a candidate for a Fellowship in the department of Medicine, the election for which by the Senate will take place next month. On the same occasion Mr. C. H. Robinson, also connected with the Ledwich School, will be a candidate for an examinership in Materia Medica. In mentioning these candidatures, it may be noted as remarkable that the Ledwich School (which has about the same number of students enrolled on its book as the University of Dublin) is the only medical institution in Ireland which has not a single teacher connected with the Royal University, either as a senator, fellow, or examiner. On the other hand, Trinity College has sixteen senators, four fellows, and two examiners; and the Catholic University three senators, ten fellows, and six examiners. The Senate will, at the end of October, elect a curator, to take care of all the University collection, museum, laboratories, &c., and who shall also be

Digitized by Google

competent to act as an examiner in some one of the experimental or natural sciences. Candidates must apply to the secretaries of the University on or before Oct. 1st.

THE EPIDEMIC OF MEASLES IN DUBLIN.

The measles epidemic, which has been prevalent in Dublin for some months, shows little signs of abatement, and up to the present the deaths have been numerous. For example, taking the thirteen weeks ending Sept. 10th, I learn that 299 persons succumbed to the disease; and as the epidemic exists in various parts of the country, the total mortality must be considerable.

BOYLE UNION.

The Boyle Guardians, in a sudden fit of economy, recently determined to give notice to their apothecary to resign, intending that their medical officers should compound the necessary medicines, thereby saving the salary of the apothecary. However, the guardians, when they came to ask the medical staff, met with a distinct refusal, as they very naturally declined to undertake additional duties which they had not contracted to perform. In this dilemma the guardians sought the aid of the Local Government Board, and requested them to sanction the proposed abolition of the office of apothecary to the workhouse and of Boyle dispensary district, in consequence of the state of the union finances, and because some adjoining unions did not possess an apothecary. The Board, however, refused on these insufficient grounds, and Dr. Todd, their inspector (to whom they referred the matter), was of opinion that it would be contrary to the interests of the sick poor to carry out the proposal. A notice of motion has been given that the clerk should again write to the medical officers, and that, should they refuse to compound medicines, they be requested to resign, and that a new election be held to fill the vacancies. The medical staff would, of course, be very foolish to adopt such a suggestion; they ought to be perfectly aware that the guardians, dare not remove them more especially as the sanction of the Local Government Board to the removal of the office of apothecary to the workhouse and dispensary district has been withheld.

Conjoint examinations for the diplomas of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Ireland will be held at the end of October or beginning of November.

Dr. Laurence Kerrigan has been elected coroner for the county of Westmeath without opposition.

Dublin, Sept. 20th.

PARIS.

(From a Correspondent.)

THE SWEATING SICKNESS.

IN the course of a long report, read at a recent meeting of the Academy of Medicine, upon the recent epidemic of sweating sickness in the central departments of France, Dr. Brouardel stated that he had made a diagnosis of the epidemic, which would prevent it being mistaken for measles in future, the eruption on the skin being much more rapid, appearing upon the second day after the premonitory symptoms have set in, while when the patient is recovering the peeling of the skin is very much more like that attending scarlet fever. Moreover, the children, who are more subject to it than grown persons, perspire very profusely, and appear to be suffering from intense oppression on the chest. There is, however, much in common between the two complaints, as the parents of children who have had measles have themselves afterwards been seized with the sweating sickness. Dr. Brouardel explains that for some reason or other the neighbourhood of Poitiers has always been very subject to it. This year it has been particularly severe, for out of 13,000 inhabitants in the district of Montmorellon 1700 were attacked, and the average rate of mortality was 12 per cent., though in some villages it reached as much as 33 per cent. Curiously enough, while in some villages twenty children were attacked to one adult, in other places more adults than children were seized with the disease. It is evidently contagious, for upon one farm fourteen people out of nineteen were seized, but there is no evidence to show that it is propagated by the water or any other liquid. It is communicated like measles or scarlatina, and the period of incubation never exceeds twenty-four hours. Dr. Brouardel, in order to check the propagation of the disease, organised, with the assistance of the house surgeons in some of the Paris hospitals, a special medical service for disinfecting the clothes and cottages in the district, the chief feature in which was the formation of a relief convoy, comprising a hand engine and apparatus for steaming clothes, bedding, &c. The epidemic has now quite disappeared.

TYPHOID FEVER IN PARIS.

There is another typhoid epidemic in Paris, due, it is alleged, to the substitution, during the recent long spell of hot dry weather, of the Seine for spring water in many quarters of Paris. On Sept. 1st there were 353 typhoid-stricken patients in the hospitals. There are now 509. The number of those who are treated in their homes is said to be very great.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Major John Stannard McAdam, to be Brigade Surgeon, vice A. S. K. Prescott, retired (dated July 26th, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Robert George Bird has been placed on the retired list of his rank (dated Sept. 9th, 1887).

ARTILLERY VOLUNTEER CORPS.—2nd Volunteer (Dorsetshire) Brigade, Southern Division, Royal Artillery: Acting Surgeon P. W. G. Nunn resigns his appointment (dated Sept. 17th, 1887).

RIFLE VOLUNTEER CORPS.—1st Clackmannan and Kinross: Acting Surgeon P. Rough, M.B., resigns his appointment (dated Sept. 17th, 1887).—1st Volunteer Battalion, the Northumberland Fusiliers: Lieutenant J. P. Elliot to be appointed Acting Surgeon (dated Sept. 17th, 1887).—1st Volunteer Battalion, the Prince of Wales's (North Staffordshire Regiment): Charles Henry Phillips, Gent., to be Acting Surgeon (dated Sept. 17th, 1887).

Obituary.

WILLIAM BLOWER, M.R.C.S., L.S.A.

THE late William Blower was born at Yardley-Hastings, Northamptonshire, on Oct. 19th, 1802. His marked abilities and love of study led his parents to choose for him the profession of medicine, and to this end he was placed with the late Mr. Aspray, of Olney, Bucks. In due time he went to London, and studied at Guy's, Webb-street, and St. Thomas's. He took his L.S.A. in 1824; and two years later, an opening presenting itself at Bedford, he settled there in practice at the age of twenty-four. After thirty years of laborious practice, with constantly increasing engagements, when fast rising in public estimation and becoming a consultant in difficult cases, especially of diseases of women, his tall and noble form was suddenly laid low with paraplegia, which in three days became complete, and, in spite of all that skill could do, the paralysis continued unrelieved. Although thus permanently confined to his couch, removed from all active life, and at times suffering much from severe attacks of pain and depression, his active and well-stored mind, aided by an exceptional memory, found abundant occupation in study, reading, and writing. His seclusion was relieved by the visits of his old friends and several former pupils, who much enjoyed a chat with him, and to hear his mature experience on scientific, medical, and other subjects. For many months his friends had noticed a gradual failure of strength, but he continued to rally from slight ailments until Thursday, the 25th ult., when attacks of lancinating pains, with restless nights and signs of failure of the heart's action, excited fears, but too soon realised, that life was ebbing out; and the heart gently ceased to beat on Aug. 30th. His faculties remained unclouded to the last. The illness just exceeded twenty-eight years. He was

Digitized by Google

within two months of completing his eighty-fifth year. He married rather late in life, and leaves a widow, but no children.

In sanitary matters Mr. Blower took a deep interest, and the subject of epidemics was his constant study. His experiences of the cholera epidemics in Bedford in 1832 and 1849, and of several severe outbreaks of continued fever in the town and neighbourhood, furnished him with a wealth of illustration now happily wanting to many others equally busily engaged in practice. He contributed valuable papers on these and other subjects to the medical journals, chiefly during his illness, when he occasionally wrote in the local papers on matters of public interest, sometimes anonymously. He took a prominent part in local politics, was a member of the corporation and of the Harpur Charity Board, and in 1853 was elected mayor. The Literary and Scientific Institution and General Library had in him one of its little band of founders. His fondness for natural history, and especially botany, incited the same love in others, and had no little to do with the formation of the Beds Natural History Society, to which during his illness he communicated some interesting papers. He was an earnest and critical Biblical student, reserved in his bearing; but those who knew him intimately recognised the sincerity of his Christian faith, so exemplified by the unmurmuring fortitude with which he bore an unusually protracted and trying affliction. He was firm in his convictions, had strong insight, a genial manner, and a disposition very unselfish and self-sacrificing. He was ever a most kind and sympathising friend to the poor, who shared equally with others his helping hand. All who knew him deeply mourn the loss of a true and valued friend.

DR. F. RICCO.

THIS eminent Neapolitan physician and alienist died on the 2nd inst., in circumstances peculiarly distressing. For the last few weeks he had been relieving his onerous duties in Naples as director of the Ospedale della Pace by running down by train to Salerno, whence, after the reinvigorating sea bath, he returned in the evening to town. He had entered the last up train shortly after 5 P.M. seemingly in good health and spirits, but at the next station after Salerno he was found by the guard dead in a first-class carriage. Every care procurable in the little town of Cava dei Tirreni (the station in question) was bestowed on him, but death, presumably from heart failure, had supervened long before he had got so far on his home journey. He was carried to the Mater Domini Hospital in Naples, whence, on the 4th, he was followed to the grave by a long train of mourners, including the Duke di San Donato, all the Neapolitan deputies and civic dignitaries then in the city, the leading medical men (professors and practitioners), and many working-men's societies, each with its special banner.

Federico Ricco, in addition to his work as director of the Ospedale della Pace, in which, it may be mentioned, he established a *clinica pædiatrica*, had also laboured much and effectively in the institution of the great inter-provincial lunatic asylum at Nocera. He had also conceived the project of erecting a special asylum for criminal lunatics, a *manicomio-carcere*; but its realisation, though actively favoured by many distinguished names in penal legislation, he had to postpone.

He was a frequent and able contributor to the literature of the profession, especially to the clinical side of medico-psychology, and the fame he thus acquired led to his admission as honorary fellow into many societies in Italy and abroad. His courtesy and his intelligence will long be gratefully remembered by all who had the privilege of accompanying him over the hospitals under his care.

He is survived by his wife, the only sister of Signor Nicotera, Minister of the Interior in the first Depretis Cabinet.

PAOLO MACCHIAVELLI.

ONE by one the physicians and surgeons whose distinction has been earned in the campaigns fought out for Italian unity are passing away. The last to swell "the majority" is the Commendatore Paolo Macchiavelli, who, in the medico-military parlance of Italy, filled the post of major-general on the army medical staff.

He was born at Sarzana, on the Riviera Ponente, on Dec. 9th, 1825. Trained for the medical profession, the revolution of 1848 found him, with many other ardent youths, eager to join its ranks; and so in that year he served as quarter-master in the column of Genoese volunteers formed under the Provisional Government of Lombardy. In 1859, the war of independence, in which King Victor Emanuel, allied with the Emperor Napoleon, took the field against Austria, drew him once more into active campaigning, and he became surgeon to the regiment of *cacciatori* (chasseurs) in the army of the Emilia. Next year he entered the Royal service as *medico divisionale* (surgeon of division), from which position he was promoted through all the successive stages, till, on November 30th last, he was appointed major-general on the medical staff, and on the same day president of the Commission of Military Hygiene.

For his services in the campaigns of 1848, 1859, and 1866, he was honourably mentioned, not only as a medical officer, but as a combatant under fire—services which, among other distinctions, procured him the orders of the Crown of Italy and of the Saints Maurice and Lazarus. "He was," says a professional compatriot, "a man of high culture and of unswerving probity: austere, indeed, but scrupulously just. He had made himself proficient in many departments of medicine; while in surgery, his special field, he possessed singular skill as an operator. Military hygiene was his favourite study, and he had earned in it a reputation which extended far beyond the Italian frontier.

His death was sudden. Passing through Genoa on his way to headquarters in Rome, he went on the 12th inst. to the public baths in the Piazza Cavour, and there, at noon, he was seized with cerebral hæmorrhage, and never afterwards regained consciousness. He leaves a widow and daughter to mourn an exemplary husband and father.

Medical News.

SOCIETY OF APOTHECARIES.—The results of the examination in Arts qualifying for registration as medical student, held in the hall of the Society on the 2nd and 3rd inst., have just been published. There were 181 candidates, and from the pass list it appears that thirty-six were placed in the second class, and eighty-two were certified as having passed in some subjects, but not in all. The next examination will be held on the 2nd and 3rd of December.

AT an estimated cost of £2723, the Bradford Town Council has decided to make additions to its fever hospital.

GREAT NORTHERN CENTRAL HOSPITAL.—An amateur theatrical performance for the benefit of the funds of the above charity was held on the lawn of Fairseat, Sir Sydney Waterlow's house at Highgate, on Saturday last.

THE GRESHAM LECTURES ON PHYSIC.—Dr. Symes Thompson commences his annual lectures at Gresham College on October 4th, and the course will be continued on the three following days.

GLASGOW ROYAL AND WESTERN INFIRMARIES.—For the benefit of these infirmaries a sum of £170 10*s.* was realised by the gate money drawn at the Children's Jubilee Fête held on Glasgow Green on the 10th inst. To this amount a sum of £30 was added by Mr. Walter Wilson, promoter of the entertainment—£100 5*s.* being thus received by each of the two institutions.

DONATIONS TO MEDICAL CHARITIES.—Mrs. Adcock of Erdington has given £1250 to be devoted to the maintenance, in the Jaffray Suburban Hospital, Birmingham, of a bed in memory of her husband and of her brother.—In addition to the contribution to the funds of the Ayr County Hospital by the Earl of Stair mentioned in our last, the sum of £1389 towards the same object has been collected by the Hon. Mrs. Vernon.

VOLUNTEER MEDICAL STAFF CORPS IN EDINBURGH.—During the last few months members of the St. Andrew's Ambulance Association have been drilling weekly in the Edinburgh Corn Exchange with the object of forming a lay company of the Volunteer Medical Staff Corps. At a recent meeting it was resolved to memorialise the Government to obtain the necessary official sanction, and to bring the matter under the notice of the Secretary of State for Scotland, the Lord Advocate, and the members of Parliament for the city.

DROWNING OF A SHIP'S SURGEON.—On the 11th inst. a body, identified at the subsequent inquest as that of Mr. James Oakley, L.R.C.S.I., was washed ashore at Millom. The deceased was surgeon to the mail steamer *Calabar*, sailing between Liverpool and Cape Coast Castle. The circumstances attending the casualty seem obscure, as the vessel appears not to have been wrecked. The coroner's jury returned the verdict of "Found drowned."

DENTISTRY IN GLASGOW.—The dental students of Glasgow have met to protest against the amount of unqualified dental practice being carried on in the city. A petition was drawn up appealing to the West of Scotland branch of the British Dental Association for protection against men who, without right or title, are practising dentistry, to the detriment of those who have spent both time and money to qualify themselves for the duties of their profession.

THE BIRTH-RATE IN FRANCE.—The French population returns for 1886 have just been issued. The births exceeded the deaths by 52,560, the smallest excess known of late years. In 1881 the excess was 108,000; in 1882, 97,000; in 1883, 96,000; in 1884, 78,000; and in 1885, 85,000. The divorces, which for the second time figure in the returns, were 2942 in 1886, against 4277 in 1885. Paris furnished 650 of them, whereas Hautes Alpes and Lozère had none, and Cantal, Savoie, and Vienne had only one each.

MEASLES AT HANWELL.—On the 19th inst., at the ordinary fortnightly meeting of the managers of the Central London School District, the clerk reported that the medical superintendent of the Hanwell Schools advised the sending of no more children from the City of London or St. Saviour's Workhouses at present, in consequence of the outbreak of measles at the schools. It was eventually, however, determined to send the children to the schools, but to prevent their intercourse with the other children already there.

MIDDLESBOROUGH TRADES COUNCIL HOSPITAL DEMONSTRATION.—A few days since the annual Trades Council Hospital Demonstration was held in the Theatre Royal, Middlesborough, the Mayor (Mr. Hinton) presiding. Addresses were delivered by Mr. Isaac Wilson, M.P., and other gentlemen. The theatre was crowded in every part, the representatives of the several trades having paraded the chief streets of the town accompanied by several bands of music. The collection in aid of the North Riding Infirmary and Cottage Hospital amounted to £12 15*s.* 7½*d.*

INTERNATIONAL SHORTHAND CONGRESS. — Many of our readers are no doubt sufficiently interested in rapid methods of handwriting to welcome the announcement that the International Shorthand Congress will assemble on Monday next, in the theatre of the Geological Museum, Jermyn-street. The meetings will be continued during the whole of next week. On the 26th, at 8 P.M., the inaugural address will be delivered by Lord Rosebery. On Wednesday, the 28th, at the same hour, a bust of Mr. Isaac Pitman, who may be said to be the father of the modern system of shorthand, will be presented to his family.

EFFECT OF QUININE ON UTERINE HÆMORRHAGE.—The new Brazilian journal, *Boletim Geral de Medicina e Cirurgia*, publishes a paper by Dr. Deocleciano Ramos on the Effect of Quinine on Uterine Hæmorrhage. He cites two cases of patients who suffered, it is true, from malaria, in whom a very few full doses—fifteen grains—of quinine served to check, and indeed to cure, violent and intractable uterine hæmorrhage. In one case iron and ergotin had been given internally, and cold injections administered, without much effect, but a single dose of quinine produced a considerable diminution in the amount of blood lost, and a second similar dose completely arrested the discharge, which did not return.

CHARTERHOUSE SCIENCE AND ART SCHOOLS AND LITERARY INSTITUTE.—The winter session of this, one of the largest science and art schools in the United Kingdom, will commence on Oct. 1st, under the presidency of the Rev. Henry Swann, M.A. Instruction of a practical character is given in most of the sciences at a very nominal fee. Day classes will also be held to prepare candidates for the London matriculation, the clerical, medical (including dental), legal, and other examinations. Students who aim at becoming proficient in chemistry (organic and inorganic) have the opportunity of working in a well-fitted laboratory, capable of accommodating sixty students. Aspirants of university honours can at a small expense be assisted in their studies. Classes for matriculation, Latin, Greek, French, German, music, and shorthand are taught by well-qualified teachers. Full particulars of the classes may be obtained from C. Smith, organising secretary.

SUICIDE IN PRUSSIA.—The following record of suicides is contained in a recent number of the *Statistischen Correspondenz*:—In the kingdom of Prussia during the year 1885 there were 6028 cases of suicide, as compared with 5900 cases in 1884, and 6171 in 1883; so that while there had been a decrease from 1883 to 1884 of 271 persons, or 4·39 per cent., the sum had risen from 1884 to 1885 by 128 cases, or 2·56 per cent. The suicides of the year 1885 are divided into 4811 men and 1257 women. In 4928 cases the motive for suicide was known, and is catalogued as follows:—1582 cases from insanity, 766 grief, 659 vice, 611 weariness of life, 477 physical suffering, 435 remorse, shame, &c. Most of these suicides—namely, 3632—ended their lives by hanging. The rest are divided thus: Drowning, 1150; shooting, 636; poison, 245; cutting the throat, 123; jumping from a height, 81; under railway trains, 71; opening a vein, 48; &c. Suicide was relatively most frequent above middle age, for 21·3 per 100,000 persons were from twenty to thirty years of age; 28·1 from thirty to forty; 39·1 from forty to fifty; 52·7 from fifty to sixty; 59·7 from sixty-six to seventy; 53·7 from seventy to eighty; and 55·2 above eighty years of age.

Births, Marriages, and Deaths.

BIRTHS.

CARTER.—On the 17th inst., at Belmont, Shipley, the wife of D'Arcy B. Carter, M.R.C.S., L.R.C.P., of a daughter.

CHEPMELL.—On the 11th inst., at Forrest-road, Edinburgh, the wife of Chas. Chepmell, L.R.C.P.Ed., of a daughter.

GLYNN.—On the 15th inst., at Rodney-street, Liverpool, the wife of T. R. Glynn, M.D., of a daughter.

HEDGES.—On the 15th inst., at Rutland House, Leighton Buzzard, the wife of J. A. Hedges, M.R.C.S., L.S.A., of a son.

MULLIS.—On the 29th ult., at Boyson-road, Walworth, S.E., the wife of George William Mullis, L.R.C.P.Lond., M.R.C.S., L.S.A., of a daughter.

PRIESTLEY.—On the 19th inst., the wife of R. C. Priestley, M.A., M.B., of Upper Berkeley-street, of a son.

ROBSON.—On the 10th inst., at 20, South-street, Durham, the wife of E. Sheddon Robson, M.R.C.S.E., of a daughter.

MARRIAGES.

ADAMS—JOYCE.—On the 13th inst., at St. Thomas's Church, Ryde, by the Rev. S. W. Stevens, Charles Edward Adams, M.B., B. Sc. Lond., M.R.C.S.Eng., of Buckhurst-hill, Essex, to Fanny, fifth daughter of Edwin Joyce, of Ryde, I. W.

ARNISON—HOLDING.—On the 20th inst., at St. Jude's, Southsea, by the Vicar, the Rev. J. S. Blake, M.A., William Christopher Arnison, M.D., of Newcastle-on-Tyne, to Kate, youngest daughter of the late Richard Holding, of Southsea.

BUSH—ROBERTSON.—On the 20th inst., at the Parish Church, Weston-super-Mare, by the Rev. F. Andrews, Rector of Kinnersley, Herefordshire, assisted by the Rev. H. Gibbs, Rector of Hutton, Somersetshire, J. Paul Bush, M.R.C.S., fifth son of the late Major Robert Bush, of Clifton, Bristol, to Laura Annie, eldest daughter of the late John (Quartus) Robertson, Esq., of Cororooke Colac, Victoria.

DELEVINGNE—YOUNGER.—On the 17th inst., at St. George-the-Martyr, Queen-square, Bloomsbury, by the Rev. H. B. C. Delevingne, cousin to the bridegroom, Henry Ferdinand Delevingne, of Kronberg, Stoke Newington-common, to Constance, elder daughter of the late Edward Younger, of 117, Leadenhall-street, E.C., and Holly Mount, Blackheath-hill.

JONES—ROBY.—On the 21st inst., at St. Michael's-in-the-Hamlet, by the Rev. Canon Burbidge, Henry Jones, Surgeon, of Upper Warwick-street, Liverpool, to Mary, youngest daughter of the late John Roby, of Rainhill.

SHIRLEY—VERE-WALWYN.—On the 15th inst., at St. Mark's, Bath, by the Rev. E. J. Wemyss-Whittaker, Matthew Bernard Shirley, L.R.C.P., M.R.C.S., of Grove House, Batley, only son of Matthew Shirley, Physician and Surgeon, Beeston-hill, Leeds, to Frances Harriette (Dollie), Vere-Walwyn, youngest daughter of the late F. A. Vere-Walwyn, Esq., of Greenheys, Manchester.

DEATHS.

ILOTT.—On the 18th inst., at Bromley, Kent, Edward Ilott, F.R.C.S., aged 60.

KILLERY.—On the 19th inst., at York-place, Portman-square, St. John Killery, M.D., Brigade-Surgeon, Medical Staff, aged 51.

QUAIN.—On the 15th inst., at Cavendish-square, W., Richard Quain, F.R.C.S., F.R.S., Surgeon Extraordinary to H.M. the Queen, aged 87.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ATKINSON, ROBERT, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Rishworth Urban Sanitary District, vice Britton, whose appointment is about to expire.

BOND, FRED. FIELDING, M.D.Ed., has been appointed Medical Officer of Health for the Rastrick Urban Sanitary District, Yorkshire, vice Britton, whose appointment is about to expire.

EMMERSON, JOHN BOLTON, M.D.Dur., M.R.C.S., has been appointed Medical Officer for the Biggleswade District of the Biggleswade Union, vice Stevens.

EVANS, WILLIAM, L.R.C.P. Ed., M.R.C.S., has been reappointed Medical Officer of Health for the Anglesey Rural, Holyhead Rural, and the Beaumaris Urban Sanitary Districts.

HINDLE, FRANCIS JOSEPH, L.R.C.P. Ed., L.F.P.S. Glas., has been appointed (*pro tem.*) Medical Officer for the Leake District of the Loughborough Union.

HIRST, ALFRED, M.R.C.P.Ed., has been reappointed Medical Officer of Health for the Prestwich Urban Sanitary District.

HOOPER, ALFRED, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for No. 2 Division of the Burton-on-Trent Rural Sanitary District.

JOHNS, WILLIAM STEPHEN, L.R.C.P., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the March Urban Sanitary District.

KARKEEK, PAUL QUICK, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the St. Mary Church and Torquay Urban Sanitary Districts.

OWEN, ARTHUR D., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to the Royal Portsmouth Hospital, vice J. O'Conor, M.D., B.Ch., promoted.

PARRY, THOMAS WILLIAM, L.R.C.P. Ed., M.R.C.S., L.S.A., has been appointed Medical Officer for the Ferndale District of the Pontypridd Union.

PAXTON, JOHN, jun., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Berwick Rural Sanitary District, vice MacKay, resigned.

SYMONS, JOHN, M.D. St. And., L.R.C.P. Lond., has been reappointed Medical Officer of Health for No. 1 Division of the Burton-on-Trent Rural Sanitary District.

THOMPSON, ABRAM, M.D. St. And., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Ulverston Rural Sanitary District.

WILSON, ALEXANDER, M.R.C.S., L.R.C.P.Lond., has been appointed Administrator of Anæsthetics to the Victoria Dental Hospital, Manchester.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BELGRAVE HOSPITAL FOR CHILDREN, Gloucester-street, S.W.—Physician. House-Surgeon. Stipend £30 per annum, with board and lodging.—Dispenser. Stipend £40 per annum.

BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Resident Clinical Assistant.

CARDIFF CORPORATION.—Medical Officer of Health for the Urban and Port Sanitary Authorities. £400 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Surgeon to out-patients.

HALIFAX INFIRMARY AND DISPENSARY.—Assistant House-Surgeon. £50 per annum, with board and residence.

HORTON INFIRMARY, Banbury.—House-Surgeon and Dispenser. £60 per annum, with board and lodging.

LIVERPOOL NORTHERN HOSPITAL.—Resident House-Surgeon's Assistant. No salary, but hospital practice and certificate of attendance, together with board and lodging.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer of the Convalescent Home at Cheadle. Remuneration £150 per annum, with board and residence.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Junior House-Physician. Also two House-Surgeons. Board, lodging, and washing.

NOTTINGHAM BOROUGH ASYLUM.—Assistant Medical Officer. Salary at the rate of £120 per annum, with apartments, board, and washing.

SOUTH STONEHAM UNION.—Medical Officer of Health. Salary £200 per annum.

WESTRAY PAROCHIAL BOARD.—Medical Officer. Besides salary, a good general practice.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

FREE PUBLIC LIBRARIES.

IN the opinion of many thoughtful people the increased and increasing facilities for the spread of national education have rendered the establishment of a free public library in every large centre of population almost a necessity. We are glad therefore to see that the residents of St. Pancras are bestirring themselves to obtain this boon for themselves and their fellow-parishioners. An appeal has been issued for £30,000 to found two principal libraries, with six or eight lending branches, and not less than 50,000 books, for the parish. Of this sum £5000 have already been received or promised.

Bangor.—The diet table forwarded us is certainly capable of considerable improvement. It is too monotonous, and there is an insufficiency of vegetable food. Besides, when meat is given only once a day, it should never be in a re-cooked form, as hashes, &c. We would suggest the following:—Breakfast: Tea, coffee, and cocoa on alternate days, with cold meat and bacon alternately. Dinner: Hot roast joint of beef and mutton on five days, boiled beef and mutton two days, with always potatoes and green vegetables; farinaceous and fruit puddings alternately. Tea: Bread-and-butter and bread-and-jam alternately. Supper: Bread and cheese and oatmeal porridge on alternate nights.

F. A. G.—If the puerperium be normal, the polypus may be safely removed at the end of the month, with antiseptic precautions. Earlier removal would be unadvisable.

X. Y.—We fear we shall be unable to find room for the paper.

OBSCURE FEBRILE SYMPTOMS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of my *confrères* would kindly assist me in the diagnosis and treatment of the following case.

A. B——, aged forty-three, a strong, healthy man, had a partial sunstroke in Canada about six years ago, and about the same time an attack of typhoid. Some six months after he first noticed that an attack of fever came on every day at 4 P.M., and lasted till bedtime. No cold, hot, or sweating stage, but a burning sensation in his feet and hands, and the heels and toes became a bright red. After some months it commenced in the face and head, which became hot and flushed. He complains of nausea and a feeling of "sinking at the stomach," with much depression. The nausea is relieved by eating. He has lost 2st. in weight. These are the only symptoms. There are no physical signs of disease anywhere. Appetite good, and digestion seemingly not in fault. The fever will suddenly leave him for a couple of weeks and as suddenly return, without any apparent cause. Quinine, arsenic, liver and digestive aids, have all been tried. Is the sunstroke or the typhoid to blame, or is the original cause of the typhoid still at work?—I am, Sirs, yours faithfully,

Sept. 20th, 1887. PUZZLED.

NATURAL REPAIR AFTER INJURY.

A VERY interesting case of this kind has (says the *Naturalists' Monthly*) been recorded by Dr. R. W. Shufeldt. A raven had its upper bill shot off in front of the nostrils. The mutilation, however, was repaired by fresh growth of the bone, followed by the horny covering of the bill, so that the bird has a very respectable stump for its use.

Mr. T. L. Biemans, M.A.—If our correspondent will take the trouble to look again at the article quoted, he will see that there is no incompatibility between the statement there made and his own. The University of Brussels publicly advertises that its medical degree is merely a scientific title. The M.D. of Berlin stands on the same footing. The degrees of Ghent, Vienna, Paris, and London, on the other hand, are of themselves licences to practise. Louvain being a free or non-State University, its degree *per se* does not constitute a licence; but we understand that a Louvain M.D. has no difficulty in obtaining the licence.

Cemetery Chaplain.—We agree entirely with the remarks of our correspondent. It is most unhealthy for dead bodies to be kept for a long time in private houses; nor ought it to be allowed, seeing that no good can come of such practice. The medical officers of health should combine to get sanctioned by usage what is allowed by law. The subject is a difficult one, however, being beset with the objections connected with the "rights of the individual."

CONSULTING SURGEONS AND THEIR PRIVATE HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I am a country practitioner, and have an extensive practice. It has fallen to my lot to treat nearly every form of surgical emergency, for which kind of practice I have felt myself fully cut out, having been a house surgeon in a large hospital and having filled various responsible hospital appointments. For some time past, I, along with many of my professional brethren, have had a deep-rooted grievance, inasmuch as frequently our patients, having been sent to consult surgeons in a large centre of population at no very great distance, have not again returned to our care. The fact being that without our consent, they have been advised to go into the said surgeons' private hospital, for, in some cases, quite trifling operations. The class of patients sent to surgeons for consultation is generally quite able and willing to pay for treatment at home, when we country surgeons would at all events receive some compensation in fees for the after treatment of our cases, for which I maintain that the majority of us are fully qualified. Instead of this we are deprived by these so-called consultants (who, by the way, are nearly all general practitioners) of the very cases in which we have a particular interest. I may mention one case which has occurred to me quite recently.

I recommended a gentleman to consult Mr.——. He did so, and was advised to go into Mr. ——'s private hospital without any reference whatever to me. My patient, however, came and informed me of the occurrence, and asked my advice. I advised him to stop at home for his operation, which he did, and I had the great satisfaction of calling in another surgeon who has no hospital, and who operated most successfully on my patient, who is now again following his usual vocations.

I must tell you that for some years past it has been my custom, on learning that a surgeon had a hospital, to discourage my patients as much as possible from consulting him, and I believe it has been my lot during the past few years to divert some scores, if not hundreds, of guineas from the pockets of those who I regard as being anything but the friends of us country practitioners.

I feel certain that the foregoing remarks will meet with a response in the breasts of very many who have suffered from what I cannot but regard as the undue greed of some who ought to have every sympathy with those who have to struggle to keep their heads above water as much as

Yours truly,

Sept. 19th, 1887. A COUNTRY SURGEON.

B.P.C. UNOFFICIAL FORMULARY.

To the Editors of THE LANCET.

SIRS,—In noticing an "advance copy" of the above in an annotation in your issue of the 10th inst., p. 536, objection is taken to the apparently cabalistic letters, "B.P.C.," which indicate the authority by whom it is issued—the British Pharmaceutical Conference, the initials of which are suggested to be used by prescribers of the formulæ as definitely indicating the preparations intended. In his conception of the idea of the formulary the letters B.P.C. were recommended by the President (Mr. Thos. Greenish) at the Birmingham meeting of the Conference last year.

I am, Sirs, your obedient servant,

WM. MARTINDALE,
Chairman of the Formulary Committee.

New Cavendish-street, W., Sept. 17th, 1887.

THE RED ANT.

To the Editors of THE LANCET.

SIRS,—I shall feel glad if any of your correspondents can give me any suggestions as to the destruction of red ants infesting parts of a dwelling-house, especially the kitchen. They are harmless, but very unpleasant.

I am, Sirs, yours obediently,

Sept. 17th, 1887. S. S.

OBSTETRICS IN MINNESOTA.

OTTER TAIL, one of the frontier counties of Minnesota (according to the *Journal of the American Medical Association*), bids fair to rival the Rotunda Hospital or the Allgemeine Krankenhaus of Vienna as a resort for aspirants for obstetrical advantages and greatness. Dr. T. G. Hutton, of Fergus Falls, writes that there are now in that county living quadruplets one week old, living triplets eight months old, living twins born of a sixteen-year-old mother, and a child twelve months old whose mother is now only fourteen years and a half old.

Mr. C. W. Steenberg.—It is usual for the police officer in charge of the case to ascertain if a witness detained in hospital is in a fit state to give evidence. We think a house-surgeon should not withhold the information from the police. It is a mere hearsay statement, and is not admissible in evidence, and is only meant for the guidance of the court in directing a remand.

L.S.A. — Intimation should have been given immediately after the change of residence had been made. See last week's LANCET, p. 587.

GENERAL HOSPITALS AND THE CLUB SYSTEM.

To the Editors of THE LANCET.

SIRS,—Permit me in the interest of the profession to publish the following instances that have lately occurred in my practice, proving the gross abuse of our hospitals and the evil of the club system.

A few days ago a lady called on me to ask my advice respecting sending two of her children, boys, into hospital for a trivial operation that would, if necessary, have been done equally well at home, either by a surgeon or even the family medical attendant. She had, I found in conversation, already sent one of her children into a local hospital not far from her residence (which, by-the-bye, is in one of the very best neighbourhoods of London, and the house rated at £250). This child, I understood, was suffering from chorea and neurotic symptoms that were, in my opinion, likely to be increased by the isolation from home rather than benefited by residence in hospital. When I expressed my surprise, she said, "My husband has subscribed very liberally to the hospital," that she had already availed herself of the charity, and I know that he had given nearly £100 last year, as well as a good annual subscription to the hospital whose aid she was thinking of procuring. This lady's object in seeking hospital treatment was that "it saved trouble at home," and she and her husband believed in the skill of hospital treatment. They had lived much abroad. I might add I know her husband to be a most liberally minded man, and was privately told that one successful year he gave as much as £500 to charitable objects.

Last autumn I attended a well-to-do warehouseman, a member of the Manchester Unity, suffering from a severe attack of psoriasis and eczema all over his body. He was living in a good neighbourhood and paying £30 or £90 a year for his house and corner-shop. He, in a grateful moment, gave me a guinea, saying, "I will give you another by-and-bye. I don't want you to attend me for the club." I thanked him, replying I would credit him with the guinea and send him a bill when well. "Oh," he said, "I don't give it as a right, and should object to be charged." "But," I replied, "you, in your position as a good tradesman, would be above being attended as a club member for 1*d.* per week." He argued, "Oh! but I shall recommend you, and will in future have you to attend my wife and family." When well, I sent him my bill, a very moderate one, and crediting him with the honorarium, and reminded him that he had expressed a wish that he did not want me to attend him with only the payment the club gave. I need hardly say he has taken no notice of my bill, and I have not seen him since, and have no doubt that I have by sending him an account made a well-meaning friend an enemy.

I enclose a note from the secretary of the lodge, who has been instructed to inform me that "all members are equally entitled to the services of the lodge surgeon;" the member to whom the secretary referred is living in a house of £40 a year, and is in a wholesale house, probably earning £200 a year or more.

The development of education, and especially the School Board, has caused quite a different class of men to join these benefit societies, especially intended only for the wage-earning class; and it appears as if, with the superior position they enjoy, but few of them have the *esprit de corps* or honourable feeling that would render them above receiving their medical and surgical skill at such a rate that must starve the profession or ultimately render only the inferior section willing to accept the useful post of surgeon to their respective lodges and to give them willing and laudable service.

I am, Sirs, your obedient servant,

Sept. 19th, 1887. FREDK. H. ALDERSON, M.D.

P.S.—I am now attending a clerk in one of the best-known private banks, who is a paying member of this lodge; but I am happy to add I have no doubt he will pay me the usual fees.

A WARNING.

DR. A. ROSS PATERSON writes to ask permission to warn medical practitioners requiring a locum tenens against a man describing himself as "Mahomet Yusif Ali Khan," and also by a not uncommon English surname with the addendum L.R.C.P.

Mr. E. T. Thring (Sydney).—Attention has been repeatedly called to the matter in our columns.

Digitized by Google

THE POLYGRAPH.

We have received a specimen of an ingenious instrument having the above name. It is, in fact, a scientific toy, by means of which a young person with a little ingenuity may produce drawings of much beauty. It would, we should imagine, be a welcome addition to the resources of the Kindergarten. It may be obtained of G. Delgado, 35, Queen Victoria-street, E.C.

Mr. Curnham Corner.—1. As the death was believed to be due in some way to the accident, an inquest was necessary. But our correspondent ought not to have made the post-mortem examination without an order; for in such cases the body is technically in possession of the coroner.—2. We are of opinion that a post-mortem examination was desirable.—3. Our correspondent cannot recover a fee for making a post-mortem examination not ordered by the coroner, but he can for giving medical evidence. If his fee for the latter is refused, he should apply to the Home Secretary.

Philalethes.—There is not, as far as we are aware, any ground for supposing that the medical legislation of foreign countries has been prompted by a wish to retaliate on this country for what our correspondent styles the "arbitrary Act" of 1858.

Dr. F. Borel.—If the paper be forwarded, it shall have attention.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you could find space for the insertion of the following in THE LANCET.

That "wise fowl, experience," teaches many things; and it is astonishing how much interest it is possible for the student of science to take in a physiological experiment when the subject is one's own *corpus vili*, the operator being nature. But in spite of the personal temporary discomfort, if it results in an increased knowledge of the means to mitigate suffering in one's fellow-creatures, this must be considered ample compensation. I presume much speciality work has its origin in personal suffering. If it were possible for the medical specialist to go through the pains of pregnancy and labour, should we have a new set of obstetrics, I wonder?

I have recently had an opportunity of studying the phenomena of *mal de mer* in my own person, and my experience has led me to the conclusion that the main factor in its production is the presence of bile in the stomach. This gives rise to a peculiar burning sensation in the epigastrium before the actual onset of vomiting, and disappears immediately after. I have never heard this sensation spoken of before; but on making inquiries among my fellow-sufferers, I found they all recognised the feeling. One gentleman who did not know what sea-sickness was told me that once he went down into the saloon to look after a relative and seeing so many ill there, he suddenly experienced this epigastric burning, which swiftly impelled him to seek the deck. The tossing of the vessel, the rolling of the waves, and the unceasing monotonous movement of all the surroundings, affording no rest for the eye, together with the momentary expectation of being ill, must have a powerfully exhausting effect upon the nervous system, and there is no cause for surprise under these circumstances that the pyloric sphincter should relax and allow of regurgitation of bile. I see no reason why we should deny to the pyloric sphincter what we accede to those of the anus and bladder. In addition to the nausea a kind of vertigo is produced by the unaccustomed blending of sea and sky, which is, however, instantaneously relieved by vomiting; and this I hold to be an objection to Dr. Gowers' theory that sea-sickness is due to oscillation in the fluid of the semicircular canals. Even if, however, this suggestion be an approximately true cause, as regards treatment we are left very much where we were before. A pad in the epigastrium might be serviceable, with an opposing one in the back; and if a mild galvanic current could be passed between the two, a beneficial result would be expected. Strychnia would probably be valuable. By pursuing this or some similar course we should, at any rate, be doing something more than merely treating symptoms.

I am, Sirs, yours truly,

Sept. 20th, 1887. J. RUSSELL HARRIS, M.D.

SALICYLATE OF SODA.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged if you or any of your readers would advise me in the following.

Is salicylate of soda supposed to be a good line of treatment in rheumatic fever? Is it contra-indicated when any cardiac mischief is present? Does it ever produce sudden death?

I am, Sirs, yours faithfully,

September, 1887. M.D.

*** Certainly. There is no method more universally employed at present. The salicylate would only be contra-indicated if there were evidence of cardiac degeneration. One or two cases have been recorded in which sudden death was attributed to the use of the drug—e.g., Goodhart, Clin. Soc. Trans., vol. xiii. But such cases are, of course, very difficult of proof.—ED. L.

STUDENTS' NUMBER: ADDENDA ET CORRIGENDA.

THE following information should, in our issue of the 3rd inst., have appeared respecting *St. Mary's Hospital*:—There are seven resident medical officers, three house-physicians, three house-surgeons, and an obstetric officer. All live free of expense in the hospital, and are appointed for six months. Clinical lectures on special selected subjects are given by the physicians and surgeons at 4 P.M. on Fridays in the winter and summer sessions. Medical practitioners are invited to attend these lectures. Special classes are held for the Preliminary Scientific Intermediate M.B. and Final M.B. Examinations of the University of London, and for the Examinations for the Fellowship of the Royal College of Surgeons. *Fees:* For attendance on lectures required by the regulations of the Conjoint Board of the Royal Colleges of Physicians and Surgeons of England to be attended in a medical school, and on hospital practice for the term specified in the same regulations, £100, paid in one sum on entering the school; or £105 paid in instalments of £40 each at the commencement of the first and of the second years of study, and of £25 at the commencement of the third year. Fee for unlimited attendance on the hospital practice and on all lectures and demonstrations given in the school, £120, paid on entering the school; or £126 in instalments of £45 at the commencement of the first year of study, and £40 each at the commencement of the first and second years. Students who have kept a portion of the course of medical study at the Universities of Oxford, or Cambridge, or elsewhere, are admitted as perpetual pupils, at a proportionate reduction, or on payment of twenty-five guineas for each year of attendance at the school. For further particulars, application should be made to the Dean, Mr. G. P. Field, or to the Sub-Dean, Dr. Phillips.

A Constant Subscriber.—The Medical Council has not the power or the means to prosecute every impudent impostor. It has authority only over medical men on the Register, and this only in a very restricted sense. The best thing unqualified assistants can do is to get qualified. Where this is impracticable on the score of age or for other reasons, the Medical Council is not likely to interfere with them if they do not engage to act independently of their principals and to take charge of branch practices.

Mr. W. Hardy.—We must refer our correspondent to our Students' Number, published on Sept. 3rd.

C.—No, a fee cannot be claimed under the circumstances.

HEADACHE DUE TO ERRORS OF REFRACTION.

To the Editors of THE LANCET.

SIRS,—To the cases of headache due to errors of refraction related by Mr. T. H. Bickerton in THE LANCET of Aug. 13th allow me to add the following.

A nun, aged thirty-eight, consulted me in December, 1881, and stated that she had entered the convent at the age of eighteen, and was set to work upon embroideries, at which she soon became very skilful, and did a great deal of fine work. When a school-girl she was accounted "dull," and had occasional attacks of headache. These attacks became gradually more frequent and severe after entering the convent. At the time of my seeing her she would arise in the morning feeling perfectly well; but by noon she would have a "bursting" headache, and by evening would be compelled to take to her bed, and would vomit and be nauseated for several hours. On Sundays and holidays—days on which she used her eyes but little—she was free from discomfort of any kind. Examining the eyes, they were found to be hypermetropic, and suitable glasses (+16) were ordered. Since wearing the glasses she has remained absolutely free from cerebral and gastric symptoms. No examination of the eye had ever been made by any of the numerous physicians she had consulted during twenty years. I am, Sirs, yours respectfully,

Chicago, Aug. 25th, 1887. EDWARD F. WELLS, M.D.

PAIN IN THE HEELS.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers could suggest the cause or treatment of the following.

A middle-aged man, seemingly in good bodily health, is crippled in walking by pain in the heels. Twelve months ago he first experienced pain in the sole of one heel, and lately it has attacked the other. The pain is brought on by walking. I can discover no local cause. The patient has always suffered from a weak circulation and indigestion, but for the last few years he has had no attacks of indigestion. Hoping to receive suggestions which will enable me to relieve the patient,

Believe me, Sirs, yours obediently,

Sept. 13th, 1887. G. P.

EXCESSIVE SALIVATION.

To the Editors of THE LANCET.

SIRS,—Can any of your readers suggest treatment for a lady about four months pregnant who suffers from excessive activity of the salivary glands, usually saturating about a dozen pocket-handkerchiefs daily, as she finds if she swallows the saliva it produces vomiting.

I remain, Sirs, yours truly.

Sept. 20th, 1887. R.C.S.

Medical Diary for the ensuing Week.

Monday, September 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, September 27.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. H. E. Armstrong: General History, Principles, and Methods of Hygiene.

Wednesday, September 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

Thursday, September 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, September 30.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Ventilation, Measurement of Cubic Space, &c.

Saturday, October 1.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Medical Diary for the ensuing Week.

Monday, October 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, October 4.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. Louis Parkes: Water Supply, Drinking Water, Pollution of Water.

Wednesday, October 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Mr. Arbuthnot Lane: What are the Chief Factors which Determine the Differences which exist in the Forms of the Male and Female Pelves?—Dr. Matthews Duncan: On Tonic Uterine Contraction without Completeness of Retraction.—Dr. John Phillips: A case of Pregnancy complicated by Secondary Hepatic Cancer.

Thursday, October 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, October 7.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Prof. H. Robinson: Drainage Construction.

Saturday, October 8.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—As illustrating the manner in which inquests are held and medical evidence given in this part of the country, I wish to direct the attention of your readers to the notes of two cases of mine which have occurred within the last eighteen months.

A little over a year ago I was called in to examine a man who was said to have cut his throat. On arriving with the policeman and examining the body I found that the man had in the first place cut his throat, and, finding his attempt at suicide ineffectual, had then immersed his head in a pool of water. I remarked to his daughter, who was standing near, that none of the important vessels of the neck were severed, and therefore that death was caused by drowning. In this case no post-mortem examination was ordered, and at the inquest the only medical evidence was given by the police constable who accompanied me, and who simply repeated what I had said to the daughter of the dead man in his (the policeman's) hearing.

In the second case the patient, a miner, was injured at his work by a fall of rock and ore on Sept. 8th. He was placed in a cart and carried home. I was in attendance on his arrival. He had sustained a fracture of the clavicle in its outer third, fracture of several ribs, with laceration of the pleura and the lung substance, which was evident by the coarse crepitation audible over the whole of the chest wall and expectoration of blood. He gradually sank and died on Sept. 11th. In this case, as in the former, no post-mortem examination was ordered, and the medical evidence was given by a miner, who said that the man died from the injuries received, and that these injuries were the collar-bone and ribs broken.

If medical men are to be treated as I have been in the above cases, I think it is about time the matter were brought under the notice of the proper authorities. I am, Sirs, yours faithfully,

Dalton-in-Furness, Sept. 26th, 1887. A. GRAY, M.B.

"EXCESSIVE SALIVATION."

To the Editors of THE LANCET.

SIRS,—In your issue of Sept. 24th "M.R.C.S." requests advice in a case of excessive activity of the salivary glands occurring in a lady four months pregnant. Were the case one of salivation unconnected with the puerperal condition he would find the use of chlorate of potassium in thirty-grain doses three times daily quite sufficient to restore the secretory equilibrium; for chlorate of potassium is a powerful regulator of the functions of the conglomerate glands, at one time repressing excessive secretion, at another restoring it to its normal condition when below par. The irregularity in the present instance is evidently due, however, to reflex disorder proceeding from ovarian or uterine irritation and concomitant glandular sympathy, just as the lacteal secretion is itself the outcome of distant organic change. I have not any doubt that the application of a small blister, say 3 in. by 1 in., over the fourth and fifth dorsal vertebræ for eight hours will as rapidly dispose of the salivary trouble as it puts an end to the reflex vomiting and the neuralgic toothache incident to the period of gestation.

I am, Sirs, faithfully yours,

Belfast, Sept. 26th, 1887. ALEXANDER HARKIN, M.D., F.R.C.S.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "M.R.C.S.," I beg permission to offer the following remarks.

Excessive salivation depends on digestive disturbance, or on exalted action from reflex irritation of salivary glands. Many different conditions may be held as causative; many different remedies have been advised. If the case is still continuing as before I advise the hypodermic injection of the solution of sulphate of atropia into the region of one or both submaxillary glands. Atropia has been experimentally proved to abolish the action of the chorda tympani on the salivary secretion. In practice good results almost always attend its use. From ·01 to ·025 of a grain of the salt may be given. But the simplest plan is to begin by injection of two minims of the four grain to one ounce solution, which will equal one-hundred-and-twentieth of a grain; this may be gradually increased to four minims, equal to one-sixtieth or more. In some cases a combination of a minim or two of the hypodermic solution of morphia will permit greater tolerance of the atropia, and aid the cure. Other remedies, all more or less useful, are, calomel, gr. ½, with gr. ½ to gr. 1 each of extract of belladonna and nux vomica; hydrarg. perchlorid. or biniodid., gr. $\frac{1}{16}$ to gr. ¼, with combination of sulphate or tartrate of iron or ferrum redactum; tincture of belladonna, gutt. 15 to 20, with potas. or sodium iodide, gr. 3 to gr. 5. But iodide must not be continued over ten days continuously. Pilocarpine has been found useful in one-twelfth-grain doses; so has ext. viburn. prunif. in gutt. 15 to gutt. 30 ter die. When the cause is more glandular reflex than gastric free doses of the bromides of potassium, ammonium, and sodium are beneficial. When the stomach is irritable the dyspepsia must be treated; bismuth with carbonate of potassium will suit one case, while another will be suited by nitro-hydrochloric or phosphoric acid. Diet is important; a few cases do best with strictly animal diet, with little or no fluid. In others peptonised milk and bland farinaceous food answer best. Iron should always be given; four grains of sulphate or tartrate, with an equal quantity of phosphate of lime, vini ferri, in drachm doses, thrice daily. Mouth washes are of little service; when carious teeth keep up glandular irritation, washes of chloralum, chloral, or boracic acid are best. One or two recent American drugs promise to be serviceable; of these, aletris formosa, in form of aletris cordial, mixed with three times the quantity of water; hazeline, half an ounce in eight ounces of water; extract. pinus canadensis, an ounce to eight or ten ounces of water, are worthy of trial. Use every two hours. In the event of no improvement from any combination of these, rectal alimentation for a day or two, and pushing the hypodermic use of atropine, with or without morphia, will probably succeed, but strength must be kept up.—I am, Sirs, yours obediently,

Beaufort-gardens, S.W., Sept. 26th, 1887. LEITH NAPIER, M.D.

"INFANTILE DIARRHŒA."

To the Editors of THE LANCET.

SIR,—The concluding portion of Dr. Hamilton's letter anent infantile diarrhœa and a milk diet contains the key as to the cause of so much illness referable to milk, and a hint as to what is, I believe, the proper and natural remedy. He says, "Dr. Vaughan suggests that no milk be used where choleraic diarrhœa occurs; but I think if the precaution be taken which I have suggested there can be little danger from the use of the child's natural food." My experience is the same as his. Brewers grains or, as he terms it, "draff" either ought not to be given as food to cows or the storage of it on the cowkeepers' premises ought to be closely supervised. It may not be generally known to the public that these grains in a very few days ferment and putrefy and that cows will eat it in that state. Can that be wholesome? An experienced farmer assures me that if horses are fed on these grains they sicken and die. In the winter months—I know it to be the case—cows are kept herded together day after day, week after week, in their stalls, in semi-darkness, and highly fed on forcing food, including grains; no exercise whatever. Can it be supposed that they can keep their health, or that a feverish or sick cow is not often milked with the rest, possibly in ignorance, during the darkness of winter mornings and dull days? One of the first of my suggestions in the treatment of infantile diarrhœa is, Cease the milk, unless I happen to know it is from a dairy where no grains are admitted. It is to the feeding and health of cows we should look, equally with milk analyses and water adulterations. There are farms where cows get proper food, air, and exercise; and the milk of these must be more wholesome than that from the yards where crowding together, no exercise, and grains are the rule.—I am, Sirs, yours faithfully,

OWEN COLEMAN, M.D.

Surbiton, Sept. 22nd, 1887. Medical Officer of Health.

"PAIN IN THE HEELS."

To the Editors of THE LANCET.

SIRS,—If "G. P." were to suggest to his patient to lower the height of the heels of his boots, and lengthen them so that they reach further under the instep, I think relief would be obtained. It should also be made clear that the length of the boot as a whole is sufficient for the man. The spring introduced by some makers might in addition prove a help to the case. Buttoned would be better than elastic-sided boots.

I am, Sirs, your obedient servant,

LEWIS W. MARSHALL, M.D.,

Sept. 26th, 1887. Surgeon, Children's Hospital, Nottingham.

To the Editors of THE LANCET.

SIRS,—I venture to suggest as a probable cause of the pain to which "G. P." refers, rheumatic inflammation of the sheath of the nerve trunk passing into the sole of the foot. I may mention that a few months since I had two cases which at first presented similar symptoms to those which he describes, both heels being affected. After some time, however, the pain in one case extended upwards in both limbs, presenting the ordinary symptoms of sciatica, in the other case only one limb was so affected. Both cases were completely cured by the administration of the iodide and bicarbonate of potassium.

I am, Sirs, yours faithfully,

London, Sept. 28th, 1887. B. HOSFORD, M.A., M.D.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "G. P.," may find that the skin of the sole of his patient's heel is thick, hard, and dry, with a tendency to peel off, and he may further find that where this hard skin joins the softer skin of the side of the foot there is a line of dull redness, from which the sweat is very freely secreted. Walking is always a cause of pain under these conditions. I have seen several cases to which this description would apply. They have all been much relieved by using the following liniment:—℞. Lin. belladon., glycer. ac. boracis, aqua, p.æ.

I am, Sirs, obediently yours,

Sept. 26th, 1887. H. P.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Guyer Hunter, London; Dr. Russell Reynolds, London; Dr. Suckling, Birmingham; Dr. Harkin, Belfast; Dr. Savage, London; Dr. Cameron, Gillies, Brockley; Mr. F. LEICESTER AND SMALL-POX.

Mr. J. T. Biggs.—It is a very roundabout way for Mr. Biggs to put questions to the medical officer of health of his own town through the columns of THE LANCET. We shall cheerfully insert any letter from Mr. Biggs which invalidates our commissioner's statements; but we want to bring him to the confession of actual facts. He has said that the immunity from small-pox enjoyed by Leicester is due absolutely to sanitary measures—i.e., as distinguished from vaccination. Our commissioner avers that the sanitary authorities are themselves revaccinated, and revaccinate all persons who have been in contact with imported cases of small-pox. We call on Mr. Biggs either to accept this statement or to disprove it. The last report of the medical officer of health of Leicester illustrates the practice followed. A case of small-pox in 1886 was introduced from Sheffield or Nottingham. "The usual prompt measures were adopted; the patient was removed to the small-pox wards, and two other persons who had been in contact with him were subjected to fourteen days' quarantine, and were revaccinated, both of whom escaped the disease; the room he had occupied was thoroughly disinfected, and the bedding he had slept on destroyed. No other case occurred." The police arrangements are admirable; but our contention is that, apart from the revaccination of exposed persons, the disease would be indefinitely conveyed. And yet Mr. Biggs has thought it fair to omit the mention of vaccination as an element in the immunity of Leicester.

A. G. C.—Several suggested remedies for sea-sickness, ice among the number, are no doubt useful in certain cases; but one of universal efficacy has yet to be found.

Finem respice.—The subject has, we think, been sufficiently threshed out.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the letter of Dr. J. Russell Harris on sea-sickness in your issue of the 24th inst., but can scarcely agree with the views of that gentleman regarding its pathology. Basing his opinion on the solitary experience of his own case, Dr. Harris seems to think that the phenomena of *mal de mer* are due to the presence of bile in the stomach, the result of relaxation of the pyloric sphincter from nervous exhaustion. As medical officer of one of the largest steamships crossing the Atlantic, I have had ample opportunity of studying this affection, and have come to the following conclusions as to its pathology:—1. That the primary cause is the motion of the ship, the contents of the stomach being shaken about, in consequence of which the food acts as a foreign body, or irritant to the gastric mucous membrane. Emesis follows, being the result of reflex action. 2. That the head symptoms are secondary, and are probably due to cerebral anæmia. 3. That the continuance of nausea, after the contents of the stomach have been rejected, is due to gastric irritation, which is proved by the fact that it can be almost invariably relieved by the application of a mustard leaf or any mild counter-irritant over the epigastrium. Except in people of a "bilious temperament," or in those who are habitually constipated, I have rarely noticed the presence of bile in the vomited matter. My experience goes to show that sea-sickness is aggravated by the following complications in the order of their frequency: chronic dyspepsia, habitual constipation, pregnancy, and previous debility from any cause. It is far more prevalent in the female than in the male sex, the ratio being about 12 to 1. It rarely occurs in children under five years of age, which I suppose may be accounted for by the fact that up to that time they are as a rule carefully fed, and their stomachs are in good order. People who are in the advanced stages of phthisis seldom suffer, and then only slightly.

With regard to treatment, I have come to the conclusion that there is no specific for sea-sickness, and that such powerful medicines as nitrite of amyl, cocaine, strychnine, &c., so far from being of service, may be positively harmful. The plan I generally adopt is as follows: If I see the patient early—i.e., before emesis has set in,—I begin the treatment with an emetic of hot water, or sea water, which I find to be the most effectual. If the case is complicated with constipation, I give usually a simple enema, as cathartics given by the mouth are never retained. Then the patient is placed in the recumbent posture with the head low, and ordered a draught containing a drachm of solution of bismuth, half a drachm of aromatic spirit of ammonia, with a minim of chloroform and ipecacuanha wine in each dose, to be repeated every two hours, with plenty of ice to suck. I think it undesirable for the patient to have liquids or food in any quantity for the first twenty-four hours, unless there are signs of exhaustion, when teaspoonfuls of concentrated beef-tea and calf's-foot-jelly, with a little *dry* champagne, are required at frequent intervals. In many cases, but especially in those complicated by pregnancy, I have found "ingluvin" in grain doses every two hours extremely successful. The head symptoms can generally be relieved by the bromides of sodium and ammonium, the potassium salt being too depressing. A firm belt with a pad in the epigastrium will sometimes act as a preventive. At best the treatment of sea-sickness is most unsatisfactory, owing to the anxiety of the friends of the patient to hasten the cure by administering some "infallible specific" which they have found successful in their own case on a previous occasion.

I am, Sirs, yours faithfully,

P. S. DONNELLAN
(Surgeon, S.S. *City of Rome*).

Liverpool, Sept. 26th, 1887.

RELATIONS OF MEDICAL OFFICERS OF HEALTH TO GENERAL PRACTITIONERS.

C. E. P.—Our correspondent, we think, somewhat misapprehends the duties of medical practitioners and medical officers of health as to cases of scarlet fever, &c. He was right in reporting the cases to the health officer, but the latter has no "authority" to have cases removed to the hospital apart from that which the sanitary body may delegate to him; and even this is absolutely limited to cases having "improper lodging and accommodation"—a term which has been held to apply to the welfare of the patient, and not to protection against infection. In such a case as is reported, and in which the parents objected to removal to hospital, the medical officer of health is helpless, except to caution against illegal exposure of infected persons or things and to order disinfection of premises and clothing as soon as the disease is over. If a desquamating child was out on errands an attempt should have been made to secure conviction under section 126 of the Public Health Act; and if the parents had been duly cautioned, the exposure could doubtless have been held to be "wilful"—a necessary condition to conviction. In the second case referred to, there was an additional duty to perform; for since the house-hold children going to school, the health authority should, under the Education Code, have given notice to the school managers that they must exclude scholars from the infected house. But our correspondent does not say that this was not done, or that disinfection is not adopted on the termination of a case of scarlet fever in the town.

Philadelphian.—The reply received by our correspondent from the Council office two months ago will apply to the present time.

R. T. W.—If the gentleman named is a certifying teacher by appointment, his certificate holds good; but not otherwise.

Mr. Wm. Robertson.—We can only suggest that our correspondent should abide by the advice of his solicitors.

Dr. T. W. Mills.—We regret we are unable to insert the communication.

Mr. William Fraser.—The preparation is known to us only by name.

Cyrus.—Such advertisement is not commendable.

THE USE OF MIDDENS IN NOTTINGHAM.

To the Editors of THE LANCET.

SIRS,—In the notice of my report for 1886 in your issue for Sept. 17th you say that you cannot altogether approve of my design for a midden-privy which it contains. I wish to point out that this design was intended only to meet the requirements of certain parts in my own district and others similarly constituted. In a large and sparsely inhabited agricultural and colliery area, with scanty means of scavenging, some form of middenstead must usually be adopted, and we may often have to consider ourselves fortunate in securing watertightness (of both roof and basin) with limited capacity and superficialness to ground surface in such a structure. The slate slab beneath the seat in my plan, to which you refer, is fixed at an angle of 120° with the horizontal floor, to throw dejecta backwards and prevent accumulation directly under the seat. The whole of the latter is made to hinge against the wall to which it is attached, and thus afford additional facility (to that of the door in the midden wall) for cleansing the interior or introducing dry earth, cinders, &c. Any further mechanism than this for securing the admixture of ashes and excreta and necessitating the intelligent co-operation of the persons whose interests are most concerned is generally out of the question. The trough or basin of concrete, lined with blue brick in Portland cement, must in most cases be of sufficient capacity to contain without overfilling at least one month's accumulation of the solid household refuse and dejecta of, say, eight adult persons (such space in this district is about thirty-six cubic feet). In cases where the coal used is hard, earthy, and extremely cheap, as with us, the amount of ash produced is enormous, and proportional space must be provided for its reception. I have endeavoured in advocating the adoption of this design to secure a practicable reform. I have, as Solon said of his laws, not given the best that could be devised, but the best that under existing circumstances could be received.—I am, Sirs, yours faithfully,

PHILIP BOOBBYER.

Nottingham, Sept. 21st, 1887.

*** We are glad that Dr. Boobbyer does not disagree with our view that his design does not in all respects fulfil the principles that should, as a rule, be aimed at. It will effect improvement; but still the chief objection to the slate slab is that it gets plastered with excreta, and these, being detained on the slab, do not mix properly with the ashes, &c. The best method, in our opinion, is to have no privy-pit beyond the space beneath the seat, and by means of a rising seat to arrange for the regular deposit of ashes &c. on the excreta day by day.—ED. L.

THE CLIMATE OF TORQUAY.

To the Editors of THE LANCET.

SIRS,—By this post I beg to send you a specimen of almond [enclosed] grown upon a tree in the public gardens here without shelter or protection of any kind since the tree was planted three years ago. It appears to me to be one of the best proofs of a mild climate that could possibly be given.

I am, Sirs, yours truly,

JOSEPH HALL, Surveyor.

Torquay, Sept. 27th, 1887.

COMMUNICATIONS, LETTERS, &c., have been received from — Mr. T. Pridgin Teale, Leeds; Dr. Dickinson, London; Dr. W. A. Mackay, Huelva; Dr. F. Borel, London; Mr. Popert, Southport; Mr. Spencer Watson, London; Dr. R. M. Ralph, Burton-on-Trent; Messrs. A. and J. Shaw; Dr. A. G. Auld, Wick; Dr. Myrtle, Harrogate; Dr. Harry Campbell, London; Mr. D. J. Stewart; Mr. Weller, Hammersmith; Mr. G. Michelmore, Tiverton; Mr. J. Carter; Messrs. Everett and Son, London; Dr. A. J. Medical Diary for the ensuing Week.

Monday, September 26.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, September 27.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour.
Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. H. E. Armstrong: General History, Principles, and Methods of Hygiene.

Wednesday, September 28.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

Thursday, September 29.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, September 30.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
THE PARKES MUSEUM OF HYGIENE.—8 P.M. Ventilation, Measurement of Cubic Space, &c.

Saturday, October 1.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months £0 16 3
To CHINA AND INDIA ..... One Year 1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 6

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

CORONERS' INQUESTS.

To the Editors of THE LANCET.

SIRS,—As illustrating the manner in which inquests are held and medical evidence given in this part of the country, I wish to direct the attention of your readers to the notes of two cases of mine which have occurred within the last eighteen months.

A little over a year ago I was called in to examine a man who was said to have cut his throat. On arriving with the policeman and examining the body I found that the man had in the first place cut his throat, and, finding his attempt at suicide ineffectual, had then immersed his head in a pool of water. I remarked to his daughter, who was standing near, that none of the important vessels of the neck were severed, and therefore that death was caused by drowning. In this case no post-mortem examination was ordered, and at the inquest the only medical evidence was given by the police constable who accompanied me, and who simply repeated what I had said to the daughter of the dead man in his (the policeman's) hearing.

In the second case the patient, a miner, was injured at his work by a fall of rock and ore on Sept. 8th. He was placed in a cart and carried home. I was in attendance on his arrival. He had sustained a fracture of the clavicle in its outer third, fracture of several ribs, with laceration of the pleura and the lung substance, which was evident by the coarse crepitation audible over the whole of the chest wall and expectoration of blood. He gradually sank and died on Sept. 11th. In this case, as in the former, no post-mortem examination was ordered, and the medical evidence was given by a miner, who said that the man died from the injuries received, and that these injuries were the collar-bone and ribs broken.

If medical men are to be treated as I have been in the above cases, I think it is about time the matter were brought under the notice of the proper authorities. I am, Sirs, yours faithfully,

Dalton-in-Furness, Sept. 26th, 1887. A. GRAY, M.B.

"EXCESSIVE SALIVATION."

To the Editors of THE LANCET.

SIRS,—In your issue of Sept. 24th "M.R.C.S." requests advice in a case of excessive activity of the salivary glands occurring in a lady four months pregnant. Were the case one of salivation unconnected with the puerperal condition he would find the use of chlorate of potassium in thirty-grain doses three times daily quite sufficient to restore the secretory equilibrium; for chlorate of potassium is a powerful regulator of the functions of the conglomerate glands, at one time repressing excessive secretion, at another restoring it to its normal condition when below par. The irregularity in the present instance is evidently due, however, to reflex disorder proceeding from ovarian or uterine irritation and concomitant glandular sympathy, just as the lacteal secretion is itself the outcome of distant organic change. I have not any doubt that the application of a small blister, say 3 in. by 1 in., over the fourth and fifth dorsal vertebræ for eight hours will as rapidly dispose of the salivary trouble as it puts an end to the reflex vomiting and the neuralgic toothache incident to the period of gestation.

I am, Sirs, faithfully yours,

Belfast, Sept. 26th, 1887. ALEXANDER HARKIN, M.D., F.R.C.S.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "M.R.C.S.," I beg permission to offer the following remarks.

Excessive salivation depends on digestive disturbance, or on exalted action from reflex irritation of salivary glands. Many different conditions may be held as causative; many different remedies have been advised. If the case is still continuing as before I advise the hypodermic injection of the solution of sulphate of atropia into the region of one or both submaxillary glands. Atropia has been experimentally proved to abolish the action of the chorda tympani on the salivary secretion. In practice good results almost always attend its use. From ·01 to ·025 of a grain of the salt may be given. But the simplest plan is to begin by injection of two minims of the four grain to one ounce solution, which will equal one-hundred-and-twentieth of a grain; this may be gradually increased to four minims, equal to one-sixtieth or more. In some cases a combination of a minim or two of the hypodermic solution of morphia will permit greater tolerance of the atropia, and aid the cure. Other remedies, all more or less useful, are, calomel, gr. ½, with gr. ½ to gr. 1 each of extract of belladonna and nux vomica; hydrarg. perchlorid. or biniodid., gr. $\frac{1}{16}$ to gr. ⅛, with combination of sulphate or tartrate of iron or ferrum redactum; tincture of belladonna, gutt. 15 to 20, with potas. or sodium iodide, gr. 3 to gr. 5. But iodide must not be continued over ten days continuously. Pilocarpine has been found useful in one-twelfth-grain doses; so has ext. viburn. prunif. in gutt. 15 to gutt. 30 ter die. When the cause is more glandular reflex than gastric free doses of the bromides of potassium, ammonium, and sodium are beneficial. When the stomach is irritable the dyspepsia must be treated; bismuth with carbonate of potassium will suit one case, while another will be suited by nitro-hydrochloric or phosphoric acid. Diet is important; a few cases do best with strictly animal diet, with little or no fluid. In others peptonised milk and bland farinaceous food answer best. Iron should always be given; four grains of sulphate or tartrate, with an equal quantity of phosphate of lime, vini ferri, in drachm doses, thrice daily. Mouth washes are of little service; when carious teeth keep up glandular irritation, washes of chloralum, chloral, or boracic acid are best. One or two recent American drugs promise to be serviceable; of these, aletris formosa, in form of aletris cordial, mixed with three times the quantity of water; hazeline, half an ounce in eight ounces of water; extract. pinus canadensis, an ounce to eight or ten ounces of water, are worthy of trial. Use every two hours. In the event of no improvement from any combination of these, rectal alimentation for a day or two, and pushing the hypodermic use of atropine, with or without morphia, will probably succeed, but strength must be kept up.—I am, Sirs, yours obediently,

Beaufort-gardens, S.W., Sept. 26th, 1887. LEITH NAPIER, M.D.

"INFANTILE DIARRHŒA."

To the Editors of THE LANCET.

SIR,—The concluding portion of Dr. Hamilton's letter anent infantile diarrhœa and a milk diet contains the key as to the cause of so much illness referable to milk, and a hint as to what is, I believe, the proper and natural remedy. He says, "Dr. Vaughan suggests that no milk be used where cholerale diarrhœa occurs; but I think if the precaution be taken which I have suggested there can be little danger from the use of the child's natural food." My experience is the same as his. Brewers grains or, as he terms it, "draff" either ought not to be given as food to cows or the storage of it on the cowkeepers' premises ought to be closely supervised. It may not be generally known to the public that these grains in a very few days ferment and putrefy and that cows will eat it in that state. Can that be wholesome? An experienced farmer assures me that if horses are fed on these grains they sicken and die. In the winter months—I know it to be the case—cows are kept herded together day after day, week after week, in their stalls, in semi-darkness, and highly fed on forcing food, including grains; no exercise whatever. Can it be supposed that they can keep their health, or that a feverish or sick cow is not often milked with the rest, possibly in ignorance, during the darkness of winter mornings and dull days? One of the first of my suggestions in the treatment of infantile diarrhœa is, Cease the milk, unless I happen to know it is from a dairy where no grains are admitted. It is to the feeding and health of cows we should look, equally with milk analyses and water adulterations. There are farms where cows get proper food, air, and exercise; and the milk of these must be more wholesome than that from the yards where crowding together, no exercise, and grains are the rule.—I am, Sirs, yours faithfully,

OWEN COLEMAN, M.D.

Surbiton, Sept. 22nd, 1887. Medical Officer of Health.

"PAIN IN THE HEELS."

To the Editors of THE LANCET.

SIRS,—If "G. P." were to suggest to his patient to lower the height of the heels of his boots, and lengthen them so that they reach further under the instep, I think relief would be obtained. It should also be made clear that the length of the boot as a whole is sufficient for the man. The spring introduced by some makers might in addition prove a help to the case. Buttoned would be better than elastic-sided boots.

I am, Sirs, your obedient servant,

LEWIS W. MARSHALL, M.D.,

Sept. 26th, 1887. Surgeon, Children's Hospital, Nottingham.

To the Editors of THE LANCET.

SIRS,—I venture to suggest as a probable cause of the pain to which "G. P." refers, rheumatic inflammation of the sheath of the nerve trunk passing into the sole of the foot. I may mention that a few months since I had two cases which at first presented similar symptoms to those which he describes, both heels being affected. After some time, however, the pain in one case extended upwards in both limbs, presenting the ordinary symptoms of sciatica, in the other case only one limb was so affected. Both cases were completely cured by the administration of the iodide and bicarbonate of potassium.

I am, Sirs, yours faithfully,

London, Sept. 28th, 1887. B. HOSFORD, M.A., M.D.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "G. P.," may find that the skin of the sole of his patient's heel is thick, hard, and dry, with a tendency to peel off, and he may further find that where this hard skin joins the softer skin of the side of the foot there is a line of dull redness, from which the sweat is very freely secreted. Walking is always a cause of pain under these conditions. I have seen several cases to which this description would apply. They have all been much relieved by using the following liniment:—℞. Lin. belladon., glycer. ac. boracis, aqua, p.æ.

I am, Sirs, obediently yours,

Sept. 26th, 1887. H. P.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Guyer Hunter, London; Dr. Russell Reynolds, London; Dr. Suckling, Birmingham; Dr. Harkin, Belfast; Dr. Savage, London; Dr. Cameron Gillies, Brockley; Mr. F. S. Barber, Bradford; Dr. Tyrrell Brooks, Oxford; Dr. Dowdeswell, London; Mr. Mortimer, Portsmouth; Dr. L. Napier, London; Mr. A. B. Reade, London; Dr. N. Kerr, London; Dr. Bell Taylor, Nottingham; Mr. S. Poynter, Hove; Mr. Reginald Harrison, Liverpool; Dr. W. Fraser, Ashburton; Messrs. Condy and Mitchell, London; Dr. W. Robertson, Newcastle-on-Tyne; Mr. Shirley

LEICESTER AND SMALL-POX.

Mr. J. T. Biggs.—It is a very roundabout way for Mr. Biggs to put questions to the medical officer of health of his own town through the columns of THE LANCET. We shall cheerfully insert any letter from Mr. Biggs which invalidates our commissioner's statements; but we want to bring him to the confession of actual facts. He has said that the immunity from small-pox enjoyed by Leicester is due absolutely to sanitary measures—i.e., as distinguished from vaccination. Our commissioner avers that the sanitary authorities are themselves revaccinated, and revaccinate all persons who have been in contact with imported cases of small-pox. We call on Mr. Biggs either to accept this statement or to disprove it. The last report of the medical officer of health of Leicester illustrates the practice followed. A case of small-pox in 1886 was introduced from Sheffield or Nottingham. "The usual prompt measures were adopted; the patient was removed to the small-pox wards, and two other persons who had been in contact with him were subjected to fourteen days' quarantine, and were revaccinated, both of whom escaped the disease; the room he had occupied was thoroughly disinfected, and the bedding he had slept on destroyed. No other case occurred." The police arrangements are admirable; but our contention is that, apart from the revaccination of exposed persons, the disease would be indefinitely conveyed. And yet Mr. Biggs has thought it fair to omit the mention of vaccination as an element in the immunity of Leicester.

A. G. C.—Several suggested remedies for sea-sickness, ice among the number, are no doubt useful in certain cases; but one of universal efficacy has yet to be found.

Finem respice.—The subject has, we think, been sufficiently threshed out.

SEA-SICKNESS.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the letter of Dr. J. Russell Harris on sea-sickness in your issue of the 24th inst., but can scarcely agree with the views of that gentleman regarding its pathology. Basing his opinion on the solitary experience of his own case, Dr. Harris seems to think that the phenomena of *mal de mer* are due to the presence of bile in the stomach, the result of relaxation of the pyloric sphincter from nervous exhaustion. As medical officer of one of the largest steamships crossing the Atlantic, I have had ample opportunity of studying this affection, and have come to the following conclusions as to its pathology:—1. That the primary cause is the motion of the ship, the contents of the stomach being shaken about, in consequence of which the food acts as a foreign body, or irritant to the gastric mucous membrane. Emesis follows, being the result of reflex action. 2. That the head symptoms are secondary, and are probably due to cerebral anæmia. 3. That the continuance of nausea, after the contents of the stomach have been rejected, is due to gastric irritation, which is proved by the fact that it can be almost invariably relieved by the application of a mustard leaf or any mild counter-irritant over the epigastrium. Except in people of a "bilious temperament," or in those who are habitually constipated, I have rarely noticed the presence of bile in the vomited matter. My experience goes to show that sea-sickness is aggravated by the following complications in the order of their frequency: chronic dyspepsia, habitual constipation, pregnancy, and previous debility from any cause. It is far more prevalent in the female than in the male sex, the ratio being about 12 to 1. It rarely occurs in children under five years of age, which I suppose may be accounted for by the fact that up to that time they are as a rule carefully fed, and their stomachs are in good order. People who are in the advanced stages of phthisis seldom suffer, and then only slightly.

With regard to treatment, I have come to the conclusion that there is no specific for sea-sickness, and that such powerful medicines as nitrite of amyl, cocaine, strychnine, &c., so far from being of service, may be positively harmful. The plan I generally adopt is as follows: If I see the patient early—i.e., before emesis has set in,—I begin the treatment with an emetic of hot water, or sea water, which I find to be the most effectual. If the case is complicated with constipation, I give usually a simple enema, as cathartics given by the mouth are never retained. Then the patient is placed in the recumbent posture with the head low, and ordered a draught containing a drachm of solution of bismuth, half a drachm of aromatic spirit of ammonia, with a minim of chloroform and ipecacuanha wine in each dose, to be repeated every two hours, with plenty of ice to suck. I think it undesirable for the patient to have liquids or food in any quantity for the first twenty-four hours, unless there are signs of exhaustion, when teaspoonfuls of concentrated beef-tea and calf's-foot-jelly, with a little *dry* champagne, are required at frequent intervals. In many cases, but especially in those complicated by pregnancy, I have found "ingluvin" in grain doses every two hours extremely successful. The head symptoms can generally be relieved by the bromides of sodium and ammonium, the potassium salt being too depressing. A firm belt with a pad in the epigastrium will sometimes act as a preventive. At best the treatment of sea-sickness is most unsatisfactory, owing to the anxiety of the friends of the patient to hasten the cure by administering some "infallible specific" which they have found successful in their own case on a previous occasion.

I am, Sirs, yours faithfully,

P. S. DONNELLAN
(Surgeon, S.S. *City of Rome*).

Liverpool, Sept. 26th, 1887.

RELATIONS OF MEDICAL OFFICERS OF HEALTH TO GENERAL PRACTITIONERS.

C. E. P.—Our correspondent, we think, somewhat misapprehends the duties of medical practitioners and medical officers of health as to cases of scarlet fever, &c. He was right in reporting the cases to the health officer, but the latter has no "authority" to have cases removed to the hospital apart from that which the sanitary body may delegate to him; and even this is absolutely limited to cases having "improper lodging and accommodation"—a term which has been held to apply to the welfare of the patient, and not to protection against infection. In such a case as is reported, and in which the parents objected to removal to hospital, the medical officer of health is helpless, except to caution against illegal exposure of infected persons or things and to order disinfection of premises and clothing as soon as the disease is over. If a desquamating child was out on errands an attempt should have been made to secure conviction under section 126 of the Public Health Act; and if the parents had been duly cautioned, the exposure could doubtless have been held to be "wilful"—a necessary condition to conviction. In the second case referred to, there was an additional duty to perform; for since the house-held children going to school, the health authority should, under the Education Code, have given notice to the school managers that they must exclude scholars from the infected house. But our correspondent does not say that this was not done, or that disinfection is not adopted on the termination of a case of scarlet fever in the town.

Philadelphian.—The reply received by our correspondent from the Council office two months ago will apply to the present time.

R. T. W.—If the gentleman named is a certifying teacher by appointment, his certificate holds good; but not otherwise.

Mr. Wm. Robertson.—We can only suggest that our correspondent should abide by the advice of his solicitors.

Dr. T. W. Mills.—We regret we are unable to insert the communication.

Mr. William Fraser.—The preparation is known to us only by name.

Cyrus.—Such advertisement is not commendable.

THE USE OF MIDDENS IN NOTTINGHAM.

To the Editors of THE LANCET.

SIRS,—In the notice of my report for 1886 in your issue for Sept. 17th you say that you cannot altogether approve of my design for a midden-privy which it contains. I wish to point out that this design was intended only to meet the requirements of certain parts in my own district and others similarly constituted. In a large and sparsely inhabited agricultural and colliery area, with scanty means of scavenging, some form of middenstead must usually be adopted, and we may often have to consider ourselves fortunate in securing watertightness (of both roof and basin) with limited capacity and superficialness to ground surface in such a structure. The slate slab beneath the seat in my plan, to which you refer, is fixed at an angle of 120° with the horizontal floor, to throw dejecta backwards and prevent accumulation directly under the seat. The whole of the latter is made to hinge against the wall to which it is attached, and thus afford additional facility (to that of the door in the midden wall) for cleansing the interior or introducing dry earth, cinders, &c. Any further mechanism than this for securing the admixture of ashes and excreta and necessitating the intelligent co-operation of the persons whose interests are most concerned is generally out of the question. The trough or basin of concrete, lined with blue brick in Portland cement, must in most cases be of sufficient capacity to contain without overfilling at least one month's accumulation of the solid household refuse and dejecta of, say, eight adult persons (such space in this district is about thirty-six cubic feet). In cases where the coal used is hard, earthy, and extremely cheap, as with us, the amount of ash produced is enormous, and proportional space must be provided for its reception. I have endeavoured in advocating the adoption of this design to secure a practicable reform. I have, as Solon said of his laws, not given the best that could be devised, but the best that under existing circumstances could be received.—I am, Sirs, yours faithfully,

PHILIP BOOBBYER.

Nottingham, Sept. 21st, 1887.

*** We are glad that Dr. Boobbyer does not disagree with our view that his design does not in all respects fulfil the principles that should, as a rule, be aimed at. It will effect improvement; but still the chief objection to the slate slab is that it gets plastered with excreta, and these, being detained on the slab, do not mix properly with the ashes, &c. The best method, in our opinion, is to have no privy-pit beyond the space beneath the seat, and by means of a rising seat to arrange for the regular deposit of ashes &c. on the excreta day by day.—ED. L.

THE CLIMATE OF TORQUAY.

To the Editors of THE LANCET.

SIRS,—By this post I beg to send you a specimen of almond [enclosed] grown upon a tree in the public gardens here without shelter or protection of any kind since the tree was planted three years ago. It appears to me to be one of the best proofs of a mild climate that could possibly be given.

I am, Sirs, yours truly,

JOSEPH HALL, Surveyor.

Torquay, Sept. 27th, 1887.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Clinical Assistant.

EASTERN DISPENSARY OF BATH.—Medical Officer. Salary £100 per annum for the first year, and afterwards to be raised to £120 if satisfaction be given to the committee. Furnished apartments, with coals, gas, and domestic attendance, are provided.

FULHAM UNION.—District Medical Officer. Salary at the rate of £40 per annum, in addition to the authorised extra fees allowed for midwifery cases, fractures, &c.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer of the Convalescent Home at Cheadle. Remuneration £150 per annum, with board and residence.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Assistant Resident Medical Officer. Board and residence in the hospital.

NOTTINGHAM GENERAL HOSPITAL.—Resident Medical Assistant. Board, lodging, and washing, but no salary.

ROYAL BERKS HOSPITAL, Reading.—Physician.

ROYAL LONDON OPHTHALMIC HOSPITAL, Blomfield-street, Moorfields, E.C.—Junior House-Surgeon. Salary £50 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

CLARE.—On August 30th, at Sutton's Pasture, Vere, Jamaica, the wife of Henry L. Clare, M.B., District Medical Officer, of a daughter.

DUKE.—On the 21st ult., at Gibraltar, the wife of Surgeon-Major Alex. W. Duke, Medical Staff, of a son,

HEDGES.—On the 15th ult., at Rutland House, Leighton Buzzard, the wife of J. A. Hedges, M.R.C.S., L.S.A., of a son.

MILLAR.—On the 22nd ult., at Sowerby-bridge, Yorks, the wife of James Millar, M.D., of a son.

PAGE.—On the 24th ult., at Old Market-street, Bristol, the wife of George Shepley Page, L.R.C.P.Ed., L.R.C.S., of a son.

WELSFORD.—On the 23rd ult., at Chaucer's House, Woodstock, the wife of G. F. Welsford, M.B., of a son.

MARRIAGES.

CROWTHER—BROOK.—On the 21st ult., at All Saints' Church, Halifax, by the Rev. J. H. Warneford, M.A., Vicar, assisted by the Rev. J. S. Lawson, M.A., LL.D., Vicar of St. George's, Barnsley, and the Rev. J. H. Williams, Curate, George Dobson Crowther, L.R.C.P.Ed., L.R.C.S., L.S.A. Lond., of Halifax, eldest son of Thomas Crowther, M.D., of Luddenden, to Edith Emily, elder daughter of Cyrus Brook, Esq., of Salterville, Halifax.

HARTLEY—BRIGGS.—On the 24th ult., at the Presbyterian Church, Hull, by the Rev. J. G. Train, George T. Hartley, L.R.C.P., L.R.C.S., L.S.A., of Spring Bank, Hull, youngest son of the late Joshua Hartley, Esq., of Stottfield House, Castleford, to Lizzie, only daughter of George J. Briggs, Esq., M.R.C.S., of Spring Bank, Hull.

JONES—HUGHES.—On the 21st ult., at the Buckhurst-hill Congregational Church, Philip William Jones, M.D., to Sarah Ann, daughter of William Hughes, Esq., of Buckhurst-hill, Essex, and Victoria-park, London.

KNOWLES—RYLANDS.—On the 22nd ult., at Christ Church, Ardsley, by the Vicar, the Rev. N. J. Lloyd Kane, M.A., Henry Knowles, L.R.C.P. Lond., of St. George's-place, Barnsley, to Malinda, the youngest daughter of the late B. Rylands, Esq., of Hunningley Villa, Ardsley, near Barnsley.

NOAD—GREEN.—On the 22nd ult., at Tavistock, Ernest Noad, M.R.C.S., L.R.C.P.Edin., to Laurie, eldest daughter of the late Rev. E. A. Green.

DEATHS.

BUSTIN.—On August 28th at Hetton-le-Hole, co. Durham, John Bustin, M.R.C.S.Eng., aged 76.

FERRIANI.—On the 24th ult., at Reggio Emilia, Italia, Alessandro Ferriani, M.D., late of Gower-street, Bedford-square, London, aged 66.

GAYE.—On the 24th ult., at Newton Abbot, Devon, Wm. Gaye, L.S.A., formerly of Minehead, Somerset, aged 93.

HAYES.—On the 18th ult., at Llandudno, John Hayes, L.S.A., L.R.C.P.Ed., of Manor House, Tittensor, Staffordshire, aged 62.

JACKSON.—On the 24th ult., at Oxford, Robert Jackson, M.D., formerly Fellow of New College, Oxford, aged 76.

OGSTON.—On the 25th ult., at 13, Albyn-terrace, Aberdeen, Francis Ogston, M.D., Emeritus Professor of Medical Jurisprudence in the University of Aberdeen. Friends will kindly accept this (the only) intimation.

PRIDHAM.—On the 28th ult., at Paignton, S. Devon, Lucy Charlotte, beloved wife of Charles Pridham, F.R.C.S., M.R.C.P.Ed., of Kensington and Paignton.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

SEA-SICKNESS: A SUGGESTION.

A GENTLEMAN signing himself "Corset," in a letter to us, strongly recommends the wearing of a pair of stays for sea-sickness. He alleges them to be not only comfortable but a "complete cure," and this not alone on his own experience of five years, but that of many of his friends. We do not venture to do more than give publicity to this suggestion, which, by the way, is not a new one. We had thought that "the better half of society," which is distinguished by wearing stays, were quite as much afflicted with sea-sickness as the stay-less half. But our correspondent would doubtless attribute this to too large a dose of his remedy, for though he eulogises, like a lady, the comfort of stays, he denounces "tightlacing."

G. A.—An honorary surgeon to a hospital cannot claim a fee for attendance upon any of his hospital patients, and the case in point forms no exception to the rule. We hope that under the circumstances the patient will make a handsome acknowledgment of the good offices of the hospital and its honorary staff.

Mr. S. Poynter.—We do not see how we can deal with a matter which is confessedly *sub judice*.

ULEXINE.

To the Editors of THE LANCET.

SIRS,—In your last issue Mr. B. H. Fenwick draws attention to the above alkaloid recently isolated by me from the seeds of the furze, gorse, or whin, mentioning that $\frac{1}{10}$ gr. in pill gave rise to suppression of urine, vomiting, and fever. Some recent experiments, however, which no doubt will be published in due course, have a tendency to show that $\frac{1}{10}$ gr. is too large a dose, giving rise in some cases to some of the symptoms described. On the other hand, $\frac{1}{20}$ gr. to $\frac{1}{15}$ gr. has so far proved an efficient diuretic as to maintain for several days an unabated effect. Might I suggest to Mr. Fenwick that he in future employ the drug in solution, not as pills. A carefully made solution is uniform in all its parts, whereas a pill is but a mechanical mixture, and however carefully made cannot for accuracy of division compare with a solution. At this hospital a solution is employed containing $\frac{1}{15}$ gr. or $\frac{1}{20}$ gr. in a fluid drachm of water. Mr. T. Christy has prepared a fluid extract of the seed. As this preparation represents the full activity of the seed, it may possibly have a different action from that of ulexine, so is well worth a trial. Recently I was informed that the furze has long been used in Scotland as a domestic diuretic remedy. Perhaps some of your readers could give authentic information on the point.

I remain, Sirs, yours truly,

A. W. GERRARD,
Pharmaceutical Chemist, F.C.S.

North London or University College Hospital, Sept. 27th, 1887.

Tunstall, 6 C. J. Weekes, 7 E. B. Hastings, 8 equal E. P. Daniell, A. M. Sully, 10 B. M. Lewis, 11 P. K. O'Brien, 12 T. W. P. Lawrence. Junior Class—Fellowes Silver Medals: Equal, G. R. Murray, W. B. Ransom; certificates, 3* J. E. Dyer, 4* G. W. Sutherland, 5* G. B. M. White, 6* R. W. Boyce, 7* E. O. Turner, 8* C. S. Dowdell, 9* H. M. Evans, 10* M. G. Foster, 11* equal B. M. H. Rogers, H. Sharman, 13* Ernest Wills, 14* D. Wright, 15* W. Gordon, 16* J. W. Higginson. Second class—H. Davis, J. P. Parkinson. Clinical Dental Surgery—Prize, W. P. May; silver medal, C. J. Weekes; certificate, 3* J. O. Tunstall. Second class—G. E. Rennie. Third class—H. Dane, R. F. Gill, F. Savery. Summer Session—Medical Jurisprudence: Gold medal, E. Deanesly. Chemistry—Gold medal, S. E. Linder; silver medal, M. L. Agarwala. Second class—B. L. Abrahams, J. C. E. Lawson, A. E. Reynolds. Third class—W. A. Perry, E. Thompson. Practical Chemistry—Senior class: Gold medal: S. B. Mitra; first silver, H. Caiger; second silver, J. Yeomans. Second class—J. B. Ramsay, A. J. Waring. Third class—H. H. Horden, H. B. Kitchin, E. S. Passmore, M. E. Paul. Materia Medica and Therapeutics—Gold medal, T. L. Pennell; silver medals (equal), G. F. Blacker, H. Caiger; certificate, 4* H. B. Kitchin. Second class—S. H. Bates, W. B. Morton, J. E. Paul. Third class—A. Stanley Jones, E. L. N. Pridmore, A. E. Reynolds. Midwifery—Senior class: Gold medal, E. Deanesly. Second class—E. P. Daniell. Junior class: Silver medals, equal, H. M. Fernando, G. W. Sutherland; certificates, 3* J. O. W. Barratt, 4* E. O. Turner. Second class: A. E. Reynolds. Third class: J. L. Firth. Pathological Anatomy—Pilliter Exhibition of £30, R. W. Boyce; silver medal, G. W. Sutherland; certificates, 3* J. P. Parkinson, 4* H. M. Fernando. Second class: Henry Sharman. Histology and Practical Histology—Gold medal, H. Tilley; silver medal, D. Drew. Second class: F. G. Bushnell, J. E. Ramsay. Third class: E. N. Smith, A. C. Stevenson. Ophthalmic Medicine and Surgery—Silver medal, J. O. Tunstall; certificates, 2* equal, H. M. Fernando, C. J. Weekes. Hygiene—Silver medal and prize, Walter Venias. Second class: J. O. W. Barratt, W. G. Earle, J. H. Garrett. Clinical Medicine—Fellowes Medals: Gold, C. H. Clayton; first silver, H. E. L. Canney; second silver, H. E. Belcher; certificates, 4* equal, Harold Dane, W. C. Carter. Second class: E. Deanesly, R. F. Gill, J. E. Gould, E. B. Randal. Junior class: Fellowes Silver Medal, W. W. Tate; certificates, 2* H. M. Fernando, 3* J. L. Firth. Second class: H. W. Elphick, A. B. Kingsford, L. W. Powell, E. H. Strong. Third class: E. Wilkinson. (* Obtained number of marks qualifying for a prize.)

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Entrance Scholarships—W. H. Gossage, £30; A. W. Harrison, £40; E. Cullinan (summer), £40. Treasurer's Prize for first winter subjects, value ten guineas—A. W. Harrison; A. T. Coleman, *proxime accessit*. President's Prize for second year subjects, value 20 guineas—H. J. Pritchard; E. C. Osborn, *proxime accessit*. Chadwick Prize, value 20 guineas—H. B. Brackenbury. Clinical Medicine Prize—W. Powell. Clinical Surgery Prize—W. Powell. Winter Session.—Class prizes and certificates.—Anatomy: Senior class, E. J. Pritchard, G. W. Simpson, *S. P. Matthews, *A. B. Vase (*equal), G. A. S. Bell, E. C. Osborn, and L. Lewis; junior class, H. C. C. De Renzi, A. W. Harrison, and A. T. Coleman. Physiology—Senior class, E. J. Pritchard, P. M. Yearsley, E. C. Osborn L. Lewis, and A. B. Vise; junior class, A. W. Harrison, A. T. Coleman, and H. C. C. De Renzi. Histology—Senior class, E. C. Osborn, E. J. Pritchard, *G. W. Simpson, *A. B. Vise (*equal), S. P. Matthews, *L. Lewis, *H. B. A. Pearson, *P. M. Yearsley (*equal). Chemistry—Senior class, A. W. Harrison, prize; C. L. Lake, A. T. Coleman. Medicine—Senior class, C. S. Vines, prize; H. J. Forster. Surgery—Senior class, F. B. Betts, prize. Summer Session: Class Prizes and Certificates: Histology—A. T. Coleman, prize; A. W. Harrison, certificate. Practical Chemistry—J. B. Byles, prize; E. C. MacLeod, E. Cullinan, C. L. Lake, and R. H. Reynolds, certificates. Pathology—F. B. Betts and W. Powell, equal, prize. Materia Medica—E. Cullinan, prize; H. C. C. De Renzi, R. H. Reynolds, C. L. Lake, W. E. Passmore, J. B. Byles, and H. C. Harper, certificates. Midwifery—F. B. Betts, prize; W. Powell, certificate. Forensic Medicine and Toxicology—A. W. Harrison, prize.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ATKIN, CHARLES, F.R.C.S., L.R.C.P.Lond., has been appointed Assistant-Surgeon to the Sheffield General Infirmary.

ATKINSON, J. MITFORD, M.B.Lond., Medical Officer to No. 3 District, St. Mary Abbott's, Kensington, has been appointed Medical Superintendent of the Civil Hospital, Hong Kong.

FORT, THOMAS, L.R.C.P., M.R.C.S., has been appointed Honorary Surgeon to the Oldham Infirmary, vice G. Thomson, M.D., resigned.

FULLER, ANDREW, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Bugbrooke District of the Northampton Union.

HERSCHELL, GEORGE, M.D.Lond., has been appointed Physician to the West-end Hospital for Paralysis and Epilepsy and Nervous Diseases.

LONGFORD, HENRY, L.K.Q.C.P.I., L.R.C.S.I., has been reappointed Medical Officer for the Sutton District of the Thirsk Union.

LYON, THOMAS GLOVER, M.A., M.D.Cantab., has been appointed Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria-park.

MACAULAY, THOMAS, M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Market Harborough Rural Sanitary District.

MC CRACKEN, JOHN, M.B., C.M.Glas., has been reappointed Medical Officer for the Kilburn District of the Thirsk Union.

MACFARLANE, A. W., M.D., F.R.C.P.Ed., has been appointed Honorary Consulting Physician to the Kilmarnock Infirmary, on resigning his appointment as Physician.

MICKLE, GEORGE, M.A., M.B., C.M.Aber., has been reappointed Medical Officer for the Pickhill District of the Thirsk Union.

MUSPRATT, C. DRUMMOND, F.R.C.S.Eng., has been appointed Assistant to the Medical Superintendent at the Champion-hill Infirmary of the St. Saviour's Union.

PARK, DAVID SCOTT, L.R.C.P.Ed., F.R.C.S.Ed., has been reappointed Medical Officer of Health for the North Division of the Houghton-le-Spring Rural Sanitary District.

PARKER, ALBANY JOHN ETHERINGTON, L.R.C.P.Ed., M.R.C.S., has been reappointed Medical Officer of Health for the South Division of the Houghton-le-Spring Rural Sanitary District.

SYMES, WILLIAM SANDHAM, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Honorary Surgeon to the Chesterfield Hospital, vice Macdougall, deceased.

THOMPSON, MAITLAND, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Blankney District of the Sleaford Union.

TWREDY, CHARLES, M.R.C.S., has been reappointed Medical Officer for the Knayton District of the Thirsk Union.

WINSLOW, L. FORBES, M.B., LL.M.Camb., D.C.L Oxon., M.R.C.P.Lond., has been appointed Physician to the West-end Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy.

IMPROVED WATER SUPPLY FOR HOLBORN. — In compliance with the request of Mr. S. Gibbon, medical officer to the Holborn Board of Works, the directors of the New River Water Company have decided in future to give a constant supply of water to the following crowded parts of the district—viz., to that portion of St. Sepulchre's, Middlesex, which is bounded by a line drawn along the centre of St. John-street, down Charterhouse-street, and then along Farringdon-road to the boundary of Clerkenwell parish; and to those portions of the liberty of Saffron-hill and of St. Andrew's Eastern, which lie between Clerkenwell-road, Gray's Inn-road, and the boundary of St. Pancras and Clerkenwell parishes. The former comprises the numerous and crowded courts that lead out of Cowcross-street, Benjamin-street, and Peter's-lane; the latter the densely populated Italian quarter around Eyre-street-hill.

PRIZES AND SCHOLARSHIPS IN THE METROPOLITAN MEDICAL SCHOLS.

The following is a list of the prizes, &c., awarded for the sessions 1886-87:—

ST. BARTHOLOMEW'S HOSPITAL COLLEGE.—Lawrence Scholarship and Gold Medal—W. H. Hamer. Brackenbury Medical Scholarship—C. P. Cresch and G. L. Turnbull. Brackenbury Surgical Scholarship—W. Balgarnie. Senior Scholarship in Anatomy, Physiology, and Chemistry—C. H. Roberts. Open Scholarships in Science—E. Lloyd Jones, H. J. Waring. Preliminary Scientific Exhibition—W. E. Sargant, C. H. Langford. Jeaffreson Exhibition—F. Mangan. Kirkes Scholarship and Gold Medal—F. E. Gibbens. Bentley Medical Prize—F. W. Andrewes. Bentley Surgical Prize—Robert Bird. Hichens Prize—E. N. Reichardt. Wix Prize—J. G. Ogle. Harvey Prize—W. M'A. Eccles, prize; 2, H. M. Bowman; 3, R. C. Bailey, A. J. Edge; 5, W. K. Hughes; 6, C. K. Bowes; 7, E. V. Hugo. Practical Anatomy, Junior—Treasurer's Prize, J. F. Nall; Lecturer's Prize (extra), A. Quennell; 3, H. J. Waring; 4, R. Brown; 5, E. R. Bastard; 6, A. G. Gane, F. C. Withers; 8, C. A, Coventon; 9, F. Mangan, J. O. Harvey; 11, J. P. Wightman. Practical Anatomy, Senior—Foster Prize, C. R. Stevens; 2, R. C. Bailey; 3, G. G. Giffard; 4, T. J. C. Keats, W. K. Hughes; 6, W. M'A. Eccles. Shuter Scholarship—A. E. Nustall, B.A.

CHARING-CROSS HOSPITAL SCHOOL OF MEDICINE.—Llewellyn Scholarship, certificate, and £25, P. J. Duncan. Golding Scholarship, certificate, and £10, Charles Gibbs. Governors' Clinical Gold Medal, P. J. Duncan. The Pereira Prize, certificate, and £5, F. Grange. Senior Anatomy—Silver medal, R. Craig Ackland; certificates, J. H. Badcock, S. N. Scott, and P. H. A. Taylor, equal. Junior Anatomy—Bronze medal, D. J. Jones; certificates, J. Mountford and J. B. Williams, equal. Senior Physiology—Silver medal, Charles Gibbs; certificates, J. H. Badcock, S. N. Scott, M. Dobbs, R. Craig Ackland, and J. F. Colyer. Junior Physiology—Bronze medal, D. C. Johnston; certificates, A. R. Colyer, J. Mountford, R. H. Collins, J. B. Williams, H. S. Baker, L. Fletcher, H. J. F. Badcock, and W. S. Mercer. Practical Physiology—Silver medal, A. H. Smith; certificates, J. H. Badcock, S. N. Scott, A. T. Collum, and F. H. A. Taylor. Chemistry—Silver medal, J. B. Williams; certificates, D. J. Jones, D. C. Johnston, J. Newton, J. Mountford, and F. C. Porter. Practical Chemistry—Silver medal, A. H. Smith; certificates, M. Dobbs, T. Constant, and F. H. A. Taylor, equal, and A. T. Collum. Medicine—Silver medal, F. Grange; certificates, P. J. Duncan and A. T. Ilott, equal. Practical Medicine—Silver medal, P. J. Duncan; certificates, F. Grange, A. T. Ilott, B. F. Jackson, and H. Parham. Surgery—Silver medal, P. J. Duncan; certificates, F. Grange, A. T. Ilott, and H. Parham. Minor Surgery—Bronze medal, H. E. Oldfield; certificates, H. A. Baker, E. W. M. Higgs, and W. A. Stephenson. Practical Surgery, a minor surgery operating case — A. H. Walker. Botany—Silver medal, F. H. A. Taylor; certificates, T. A. Goard and D. C. Johnston. Materia Medica—Silver medal, M. Dobbs; certificates, P. W. J. Webb, F. B. Reilly, and W. J. Bebb. Midwifery—Silver medal, A. T. Ilott; certificate, A. E. Baker. Forensic Medicine—Silver medal, G. Barton; certificates, B. F. Jackson, S. N. Scott, and A. T. Ilott. Pathology—Silver medal, A. T. Ilott. Dental Surgery—First prize, certificate, and £6 6s., A. W. Frost; second prize, certificate, and £1 4s., C. R. Morley; certificate, A. H. Smith.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The Brackenbury Prize in Medicine and the William Brown Exhibition of £10 per annum, for three years, Ernest C. Cronier Lancaster; the Brackenbury Prize in Surgery, and the Treasurer's Prize, Frederick William Parker; the Thompson Medal, Arthur Henry Ward; Sir Benjamin Brodie's Clinical Prize in Surgery, not awarded; the Acland Clinical Prize in Medicine, not awarded; the Henry Charles Johnson Memorial Prize in Anatomy, Henry Smith Barkworth.

GUY'S HOSPITAL MEDICAL SCHOOL.—Treasurer's Gold Medal for Clinical Medicine—Theodore Fisher. Treasurer's Gold Medal for Clinical Surgery—Arthur Henry Williams. Gurney-Hoare Prize for Clinical Study—Sidney Washer and Robert Capes (equal). Beaney Prize for Pathology—Theodore Fisher. Mackenzie-Bacon Prize for Ophthalmoscopy — Thomas Halliwell. Mackenzie-Bacon Prize for nervous diseases—Ernest Henry Starling, Michael Harris Prize for Anatomy—Frederick Hall. Fourth-year students—Arthur Edward Poolman, first prize, £25; Walter Fisher, second prize, £10. Third year students—Alfred Parkin, first prize, £25; Robert Devereux Mothersole, second prize, £10. Second-year students—Frederick William Hall, £17 10s., and John Fawcett, £17 10s., equal. First-year students—John Henry Bryant, first prize, £50; Bertram Whewell Hogarth, second prize, £25; Arthur Stanley Wohlmann and William Gusterson Rogers, certificates. Open Scholarship in Arts—Frederic Hewlett Brown and George Marlow Pratt, equal. Open Scholarship in Science—Bertram Whewell Hogarth.

KING'S COLLEGE. — Winter Session: Jelf Medal—Owen le Mare Theobalds. Warneford Scholarship—Class 2, Thomas Boswell Beach. Anatomy—H. Lumbert Lack, prize; Hugh James Playfair, certificate. Comparative Anatomy—William Robert Smith, prize; Thomas Grigor Brodie, certificate. Physiology—Henry Stephen Saviffer, prize; Algernon Wilson Lyons, certificate. Chemistry—H. Lambert Lack, prize; Algernon Wilson Lyons, certificate. Medicine—Owen le Mare Theobalds, prize; Jeremiah Penny, certificate. Clinical Medicine—Thomas Boswell Beach, prize. Surgery—George Lenthal Cheatle, prize; Howard Percy Ward, Owen le Mare Theobalds, and Jeremiah Penny, certificates. Clinical Surgery—Jeremiah Penny, prize. Summer Session: Practical Physiology, not awarded. Practical Chemistry—Thomas Grigor Brodie, prize; Robert Francis Chance and Arthur Robert Savell, certificates. Botany—A. R. Savell, qualified for prize; A. Fadelle, prize; Arthur Whitfield, certificate. Tanner Prize—H. P. Ward. Practical Biology—W. R. Smith, prize. Pathological Anatomy—Owen le Mare Theobalds, prize; R. T. Hewlett, certificate. Forensic Medicine—T. B. Beach, prize; John William Brodie-Innes, certificate. Obstetric Medicine—B. H. Andrew, prize; A. H. Cheatle, certificate. Materia Medica—L. V. Cargill, prize; H. S. Sandifer and T. L. Lack, certificates.

LONDON HOSPITAL MEDICAL COLLEGE.—Entrance Science Scholarships for proficiency in the subjects required for the preliminary scientific M.B. examination at the University of London—£60 scholarship, W. H. Sturge. £40 scholarship, A. H. Smith. Buxton Scholarships for proficiency in the subjects required for the preliminary examinations—£30 scholarship, K. M. Mackenzie; £20 scholarship, P. A. Green. Clinical Medicine—£20 scholarship, given jointly by the House Committee and the Medical Council, C. R. Killick; certificate, B. Walker. Clinical Surgery—£20 scholarship, given jointly by the House Committee and the Medical Council, E. O. Ashe; certificates, O. M. Jones, B. Walker. Clinical Obstetrics—£20 scholarship, given jointly by the House Committee and the Medical Council, J. H. B. Jarvis; certificate, E. O. Ashe. Duckworth Nelson Prize—B. Walker; certificate, O. M. Jones. Letheby Prize, for proficiency in Chemistry, £30—H. E. Skyrme; certificate, J. N. Collins. Anatomy, Physiology, and Chemistry, £25 scholarship given by the Medical Council—D. Brown; certificate and £15 honorarium, B. J. Hicks; certificate and £10 honorarium, S. H. Raynes. Anatomy and Physiology, £20 scholarship given by the Medical Council—F. J. W. Porter and W. H. Sturge (equal), scholarship divided. Dressers' prizes for zeal, efficiency, and knowledge of minor surgery, given by the House Committee—£15 prizes, S. H. Raynes and R. W. Woodall; £10 prize, G. F. Oldham.

LONDON SCHOOL OF DENTAL SURGERY.—Saunders Scholar, J. H. Badcock; prize given by Messrs. Ash and Son, J. H. Badcock. Winter Session—Metallurgy: First prize, J. H. Badcock; second prize, F. Lonnon; certificates, A. W. Frost, C. R. Morley, B. Saul. Mechanical Dentistry: First prize, G. Seymour; second prize, R. H. Bates; certificates, H. A. Washbourn, A. W. Frost, C. R. Morley. Summer Session: Dental Surgery: First prize, J. H. Badcock; second prize, C. R. Morley; certificates, J. F. Colyer, R. H. Bates, H. A. Washbourn, W. H. Dolamore, F. A. Harsant. Dental Anatomy: First prize, J. H. Badcock; second prize, W. H. Dolamore; certificates, J. F. Colyer, F. A. Harsant, R. H. Bates, H. A. Washbourn, C. R. Morley. Operating Prize: First prize, G. Seymour; second prize, R. A. Colyer; certificates, C. R. Morley and H. Picton. Students' Society's Prize, awarded for paper on Dental Anæsthetics, A. T. Croucher.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Summer Session, 1886. Second year.—Midwifery, prize, F. W. Lewitt; certificate, W. S. Sharpe. Medical Jurisprudence, prize, F. W. Lewitt and P. J. Kingston (equal); certificates, W. F. Sharpe, G. Watson, and J. Griffith. First year.—Materia Medica, prize, R. H. Cole and H. A. Caley (equal); certificates, G. A. Simmons and T. Atwood. Botany—prize, V. W. Low and H. F. Mantell (equal); certificate, R. H. Cole. Practical Chemistry—prize, H. Tibbits and J. C. Wood (equal); certificates, R. D. Cox, B. J. Finch, and H. L. Hatch. Histology—first prize, G. A. Simmons; second prize, H. A. Caley; certificates, R. H. Cole, A. E. Shaw, W. T. Atwood, and W. Stocker. Winter Session, 1886–87. Third year.—Medicine, prize not awarded; certificate, F. W. Lewitt. Surgery—prize, P. J. Kingston; certificate, F. W. Lewitt. Practical Surgery—prize, F. W. Lewitt; certificates, G. C. Davis, G. Watson, W. S. Sharpe, and P. J. Kingston. Pathology—no award. Third and fourth years.—Clinical Medicine—prize, not awarded; certificates, J. T. Bays and F. W. Lewitt. Clinical Surgery—prize, J. T. Bays; certificates, G. C. Davis, F. W. Lewitt, W. S. Sharpe. Prizes in Ophthalmology of £10 10s. each—H. C. Barr and G. C. Davis. Pathology Scholarships—J. T. Bays and N. C. Ridley. Second year.—Anatomy, prize, H. A. Cayley; certificates, R. H. Cole and W. Stocker. Physiology—prize, H. A. Cayley and R. H. Cole (equal); certificate, T. Atwood. First year.—Anatomy, prize, L. Rogers; certificates, G. Winter and H. L. Hatch. Physiology—prize, G. Winter and A. W. Herbert; certificates, F. G. Harvey, L. Rogers, F. Harris, A. Thorne, and A. K. Barrett. Chemistry—prize, L. Rogers and G. Winter (equal); certificate, L. E. Parkhurst.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Broderip Scholarships for the best examination at the bedside and in the post-mortem room: First, W. H. Vickery; second, E. E. Lewis. Governor's Prize: J. Gordon. Hetley Prize: J. A. Hutton. Exhibition in Anatomy: First year, E. C. Long. Lyell Medal: J. K. Couch. Entrance Scholarships: First, A. Lawson; second, E. Rock. Exhibition: H. B. Prynne. Prizes—Medicine, J. Gordon. Surgery: G. Colborne and B. H. Deare (equal). Practical Medicine and Therapeutics: A. E. Watson. Practical Surgery: J. K. Couch. Practical Midwifery: R. F. Thomas. Anatomy: H. A. Daniel. Physiology: J. K. Clarke. Chemistry: F. Harsant. Dissections: J. K. Clarke. Pathological Anatomy: J. K. Clarke. Midwifery: J. E. Hancock. Forensic Medicine: G. Colborne. Materia Medica: C. W. Crasweller. Practical Chemistry: W. A. Hampton. Practical Physiology: C. E. Soulby. Psychological Medicine: G. Colborne. Certificates of Honour (in order of merit): Medicine, E. E. Lewis, J. A. Hutton, and R. F. Thomas (equal). Surgery: J. Gordon, H. C. Fox. Practical Medicine and Therapeutics: H. C. Fox and A. J. Hutton (equal). Practical Surgery: J. A. Hutton, G. Colborne, B. H. Deare. Practical Midwifery: G. Colborne, H. Daniel. Anatomy: J. K. Clarke, J. E. Hancock, E. G. Cameron, and E. E. Norton (equal). Physiology: H. A. Daniel, J. E. Hancock. Chemistry: H. V. Prynne, E. Jones, S. D. Timms. Pathological Anatomy: J. Gordon. Midwifery: J. K. Clarke H. Daniel, C. H. Fazan. Forensic Medicine: J. W. Gill, C. E. Bennett. Materia Medica: G. D. E. Jones and Evan Jones (equal), and S. C. Smith. Practical Chemistry: H. V. Prynne and A. Lawson (equal), G. W. Barber and E. A. Rock (equal), C. W. Crasweller and Evan Jones (equal), H. E. Pittway, D. Phillips, C. E. Soulby, S. D. Timms, and A. B. Williams (equal). Practical Physiology: W. H. Gibson.

NATIONAL DENTAL HOSPITAL COLLEGE.—Rymer Medal: T. S. Minett. Dental Anatomy—Prize: T. S. Minett; certificate, W. Rushton. Dental

Digitized by Google

(Mr. J. Marshall rearranging that portion descriptive of the arteries from Quain's own work upon the arteries), subsequently of Mr. Ellis, and more recently of Allen Thomson, Schäfer, and Thane, is familiar to all students reading for the higher qualifications. Mr. Quain's elaborate treatise on the "Anatomy of the Arteries of the Human Body, with its Applications to Pathology and Operative Surgery," with folio plates drawn from actual dissections by Joseph Maclise, F.R.C.S., will ever rank as a classical work. In addition Mr. Quain was the author of "The Diseases of the Rectum"; "Illustrations of a peculiar Bleeding Tumour of the Rectum"; and also of several minor works and pamphlets on the professional cabals and scientific questions of the day. The late Sir John Quain, the well-known judge, was his younger brother, and it is reported left him a considerable fortune.

In 1861 Mr. Quain married Viscountess Middleton, who died in November last. For years, with the exception of last year, he had passed the winter months in the south of France. In conversation he entered very fully and clearly into the subject under discussion, usually expressing his opinions in the terse and trenchant manner in which he had lectured more than forty years ago. Every word seemed to be thoroughly weighed, and the same kind of over-caution in not committing himself to more than he wished was remarkable. He was naturally intensely reserved, and he made but few friends. In his early professional life he frequently attributed wrong motives to colleagues and others, or misunderstood them, owing to his firm conviction that he took the right and just view of a question, and to his not being able to see that anyone else could honestly entertain a different view. He firmly defended those whom he thought unjustly attacked. On the other hand, he could never see anything good in an individual to whom he had taken a dislike, but then he always believed the dislike to be well founded. Of late years, however, the asperities of his character were materially smoothed down.

His death, which occurred at his residence in Cavendish-square, at the ripe old age of eighty-seven, was due to cystitis, arising, it was believed, from the presence of a stone in the bladder, but he would not allow Sir Henry Thompson to sound him. Sir Henry, it may be mentioned, had some ten years previously successfully crushed a small stone which was then affecting Mr. Quain's health. In his illness he was also attended by Sir William Jenner, Sir James Paget, Mr. Marshall, Dr. Hare, and Dr. Douglas Powell. The funeral took place on the 21st ult. at the Marylebone Cemetery, Finchley, the service being conducted by the Rev. J. D. Stewart, M.A., in the presence of many of the old friends of the deceased surgeon, as we stated last week.

Medical News.

THE annual church parade of friendly societies on behalf of the Exeter and Torbay hospitals took place at Brixham on the 25th ult.

IT has been decided to hold the annual meeting of the members of the Hull Sanitary Association on the 19th inst.

THE Hospital Saturday movement was adopted in Salisbury for the first time on the 24th ult. The collection realised about £40.

THE foundation stone of the Ashburton and Buckfastleigh Cottage Hospital was laid on the 19th ult. by the president, Mr. Bastard. The estimated cost of the new building is £1240.

THE annual house-to-house collection in aid of the Lincoln County Hospital was made in Lincoln on the 24th ult. The sum realised was £114, as compared with £124 last year, and £134 in 1885.

PRESENTATION.—On the 20th ult., Dr. Alexander William Macfarlane was, on the occasion of his leaving Kilmarnock for the south of England, entertained at dinner, and presented with a silver-gilt dessert service, a Buhl clock, and a diamond pendant for Mrs. Macfarlane, as a mark of the high esteem in which he is held by the inhabitants of Kilmarnock and district.

THE Jews of Birmingham have arranged to have a special service on Hospital Sunday, instead of on the preceding Saturday, as heretofore, "so that they may join with their Christian brethren in making the collection on that day."

BEQUEST.—At the weekly meeting of the Board of St. Mary's Hospital, Quay-street, Manchester, on the 20th September, a communication was received from the executors under the will of the late Mr. Elkanah Armitage, intimating a bequest to the hospital of £250 free of legacy duty.

AT an inquest on the 22nd ult. on the body of a man who had died at the Bristol General Hospital the jury returned a verdict of death from fatty degeneration of the heart, accelerated by chloroform being administered before an intended operation, and exonerated the medical attendants from all blame.

THE DORSET COUNTY HOSPITAL.—For some time past considerable difficulties have been experienced by the governors of this institution in the matter of the strained relations between the house surgeon and the matron. The difficulty appears to have arisen owing to the duties and positions of both officers being not clearly defined in the rules, and a committee has been appointed for the purpose of thoroughly revising them.

CENTENARIANS. — An inmate of the Swansea Workhouse, a Mrs. Jones, reached her 105th year on Sept. 24th.—An inmate of Bromley Infirmary, a Mrs. Waller, is now 107 years old. She possesses all her faculties, and when she was ninety years of age was accustomed to turn a mangle for a living.—The death was recorded on the 28th ult. of Mr. Thomas James, an old and respected inhabitant of Abercarne, at the age of 100 years. Mr. James was in possession of all his faculties to within a few days of his death.

THE RED CROSS CONFERENCE.—At the meeting, on the 23rd ult., of this conference, which has been held at Carlsruhe, a resolution was adopted requesting the States and associations which have adhered to the Geneva Convention to carry out the antiseptic treatment of the wounded as soon as they have been removed from the line of battle. It was further decided to thank the various Governments and railway companies for the gratuitous transportation of provisions for the benefit of the wounded, and to express a wish for the generalisation of those facilities.

THE WASTE OF FISH.—A correspondent of a contemporary calls attention to the enormous waste of fish which occurs throughout the year, and wonders whether it is absolutely unavoidable, and whether no means are practicable for bringing it while yet wholesome within reach of our starving poor in the East-end and elsewhere. It may be mentioned that the cost of sending a ton of goods from London to India *vid* the Suez Canal per steamer (a distance of about 7500 miles) is 10*s.* to 12*s.*, while the railway charge on a ton of fish from St. Ives, Cornwall, to London (a distance of 320 miles) amounts to from £4 to £7.

BURIAL REFORM.—Lord Basing, the President of the Sanitary Institute of Great Britain, has received the following letter from the secretary of the Church of England Burial Reform Association: "Your lordship's attention and that of the Sanitary Institute is respectfully invited to the fact that in many places the dead are imperfectly buried in strong, durable coffins in vaults, or in already crowded graves, each of which methods of disposing of the dead, by generating poisonous gases, is a source of danger to the living. The Burial Reform Association therefore earnestly ask your co-operation in their efforts to bring back the nation to the adoption of the mode of burial unmistakably indicated in the burial service—viz., timely burial in the soil, with as little as possible intervening to prevent the air from gaining access to the body through the earth above and exercising its purifying and disintegrating action. Your attention is also called to the resolution passed by the council at a recent meeting: 'The time has come when a united effort ought to be made to put a stop, as far as possible, to the dangerous and utterly indefensible practice of storing up, near great populations, vast accumulations of human remains in every stage of arrested and prolonged decay.'"

Digitized by Google

dropping in. True, there is the shadow of cholera hovering near, and even the undoubted importation of sporadic cases into the city, but these have remained sporadic merely, and the efforts put forth by the superintendents and staff of the several hospitals, and above all by the assessor of the Health Bureau (Dr. G. Bastianelli), quite explain the reassuring returns of the last fortnight. The Manicomio, or lunatic asylum of the Santo Spirito, in Trastevere, was, strangely enough, the scene of the graver "casi sospetti"; and the absence on sick leave of its able director (Dr. Fiordispini) awoke uneasy anticipations as to the progress the malady, if unchecked, might make. Fortunately, the vice-director (Dr. Solivetti), whom his principal had left in charge, showed a skill and an energy quite equal to the emergency; the cases were promptly treated and isolated, with the result that fourteen days have now elapsed, and there is not the faintest symptom of cholera or even cholerine in the whole extensive "stabilimento." The Marchese Gravina, Prefect of Rome, paid a long and searching visit to the asylum, and expressed his satisfaction with the state in which he found it, as well as with the precautions that had been taken; and within the last day or two a commission of inquiry, acting on his instructions, repeated the visit with not less reassuring results. Nothing, moreover, can exceed the promptitude with which Dr. Bastianelli makes himself cognisant of cases having even a remote resemblance to cholerine. The telephone, by his express orders, is in constant activity between the various sanitary stations and the central office, and, in the almost exaggerated scrupulosity of his reporters, diarrhœas which have no choleraic character whatever are announced at his office, and only ascertained in their reality by an immediate and sometimes prolonged investigation on the spot. By the time that cholera has fairly disappeared for the winter, he fully expects to be congratulated on the demonstration that Rome, in von Pettenkofer's phrase, is exempt, so far as cholera is concerned, from the *genius epidemicus*, an exemption in former years manifested by her freedom from the malady in spite of the influx of thousands of refugees from the cholera-infected Neapolitan Riviera; while he may also succeed in confirming Tommasi-Crudeli's doctrine, that since the great cholera invasion of fifty years ago, in which Rome had her full share, there has been a progressive reduction of receptivity as regards the disease, each visit showing a smaller number of victims as well as a milder *ensemble* of symptoms, till the expectation may almost be justified that, like the pestilences of antiquity and the epidemics of the middle ages, it may ere long perish for want of pabulum.

Obituary.

RICHARD QUAIN, F.R.C.S, F.R.S.

MR. RICHARD QUAIN, whose death on the 15th ult. we announced in our last issue, was born at Fermoy, county Cork, in 1800, his father being a retired gentleman living upon a small estate which he farmed. The subject of our notice obtained his elementary education at a private school in the neighbourhood of his native town, and commenced his professional career by serving an apprenticeship in Ireland. At the expiration of his indentures he came to London and studied at the Windmill-street and Aldersgate Schools of Medicine, establishments which at that time enjoyed a well-deserved reputation. His elder brother, Jones Quain, was a lecturer at the latter school. After completing his courses of lectures at these schools Richard Quain proceeded about the year 1825 to Paris, where he attended the lectures of Mr. Richard Bennett, a private lecturer on anatomy, an Irishman and a friend of his father, and after a time was chosen by Mr. Bennett to assist him in the dissecting room. In 1828, when the University of London, now University College, was founded, Mr. Bennett was appointed Demonstrator of Anatomy in the new institution; and Mr. Quain, who in the same year became a Member of the Royal College of Surgeons of England, accompanied his patron to England, and acted as his assistant, in conjunction with Mr. Benjamin Phillips, in the discharge of his new duties. In 1830 Mr. Bennett died, and Mr. Quain became Senior Demonstrator of Anatomy, Sir Charles Bell being Professor of Anatomy and Physiology. Subsequently Sir Charles Bell severed his connexion with the College, and in 1832 Mr. Quain was appointed Professor of Anatomy, his eldest brother, Dr. Jones Quain, being brought from the Aldersgate School to fill the post of Professor of Physiology. The late Sir Erasmus Wilson acted as Prosector to Dr. Jones Quain, and Messrs. Morton and G. Viner Ellis as Demonstrators to Mr. Richard Quain. Mr. Morton retired from this position on being appointed assistant surgeon to the hospital, and soon afterwards died; but Mr. Ellis still survives, enjoying the pleasures of country life in Gloucestershire. In 1834 Mr. Quain was appointed assistant surgeon to the North London Hospital (by which name University College Hospital was then generally known); Mr. Samuel Cooper and Mr. Liston were the surgeons, the former being Professor of Surgery and senior surgeon, and the latter being Professor of Clinical Surgery. The good policy of Lord Brougham (the President) and the Council of the College in inviting Liston from Edinburgh to become surgeon in the new hospital was soon evident by the large class of students who were attracted to the institution. At the date of Liston's arrival in London there were stormy times at University College, the professors and lecturers being divided into two factions, provoking earnest rivalry, and in some cases bitter animosity. The pages of THE LANCET at that time, more than half a century ago, were frequently occupied by accounts of these dissensions, Richard Quain taking an active part on one side, and his brother Jones Quain occupying an equally conspicuous position on the opposite side. Shortly after Liston's arrival in London, the fame of Dr. Sharpey, at that time an extra-mural teacher of Physiology in Edinburgh (Mr. Syme lecturing on Anatomy), having reached London, Mr. Quain paid a visit to the northern capital and attended Dr. Sharpey's lectures *incognito* for the purpose of ascertaining whether the reports of his excellence were correct. The result of this visit was speedily seen in Dr. Sharpey's appointment, on the retirement of Dr. Jones Quain from the chair of Physiology, to that vacant post; and we doubt if any of the older medical schools could show such an array of distinguished teachers as at that time adorned the school in Gower-street. It may be mentioned that Professor Grant occupied the chair of Comparative Anatomy, Professor Graham that of Chemistry, and Dr. Elliotson that of Medicine.

In 1843 Mr. Quain was nominated in the first list of Fellows of the Royal College of Surgeons under the new Charter, and in 1850 he was appointed full surgeon to the hospital. On his retirement from this position in 1866 he was made Emeritus Professor of Clinical Surgery. In 1854 he was elected a member of the Council of the Royal College of Surgeons, in 1865 a member of the Court of Examiners, and in 1868 he was appointed President. In 1869 Mr. Quain delivered the Hunterian Oration, the subject of his address being "On some Defects in General Education." He represented the College in the General Medical Council from July 14th, 1870, to June 14th, 1876, when he resigned. He occupied the position of an auditor of the English Branch Council, and was a member of the Finance Committee from 1875 to 1876. He took considerable interest in the question of the Visitation of Examinations, was a member of a committee on this subject, and proposed (unsuccessfully) in 1873 a resolution, which was afterwards adopted, that some of the visitors might be persons not members of the Council. He was a member in 1875 of a committee that considered the question of the admission of women to the profession. Some years ago Mr. Quain was appointed Surgeon-Extraordinary to the Queen.

Richard Quain, although not eloquent, was a good lecturer, his concise and clear method being very impressive, his capacity being more fully recognised in the lecture room than in the hospital wards, where, as was perhaps natural, the majority of operations fell to the share of Liston. The difference in the characters of the two fellow professors—Sharpey and Richard Quain—was well known to the students who attended their lectures by their respective habitual interjections while lecturing. Sharpey used often to say, "You see, gentlemen, in a manner, so to say, the phenomena," &c.; while Mr. Quain's favourite expression was, "The fact is, gentlemen," &c. He improved greatly the work of his brother, Jones Quain, on Anatomy, which, under the combined editorship of Mr. Quain and Dr. Sharpey

Digitized by Google

scopes. When touched they rise automatically to the ceiling, and discover the microscopes, free from dust and adjusted for immediate use. Every kind of incubator, steriliser, and culture apparatus for bacterial research is to be found in these rooms, and from the amount of material present it would appear that more than one research is already in progress. In the whole premises there is accommodation for about a score of workers, who will be received into the institute free of charge, having also the ordinary laboratory requisites supplied to them gratis. It is stated that already over a dozen applicants have entered claims for the advantages so generously offered, which shows how actual a *raison d'être* the laboratory possesses, and how powerful an influence it is likely to have in realising the intention of its founders.

THE CITY FEVER HOSPITAL.

Arrangements were made several months ago by which medical students were admitted to the Fever Hospital, which is under municipal management, for the study of infectious diseases. It is now complained that the class for whom the concession was made are not in the least availing themselves of these opportunities. This may be largely true, and if it is so, the reason is not far to seek. The students have so many compulsory subjects, that they can hardly find space in their crowded curricula for a subject upon which they are not examined clinically, of which a few days' reading at home gives them a sufficient grasp for examination purposes, and which in itself has the disadvantage of personal risk. In the old days this was the main risk attaching, in the estimation of the public, to "walking the hospitals"; and students whose attention is attracted by the publicity the question has now gained in Edinburgh will doubtless be reminded that, in the days preceding the isolation and systematic separate treatment of fever cases, their predecessors ran this risk cheerfully and as a matter of course.

POST-GRADUATE LECTURES.

The post-graduate course of lectures is proving no less a success this year than it did in 1886. About 100 medical men from all parts of the country and from abroad are taking part in the courses, and evincing approval of the extended scale on which they are this year conducted.

Edinburgh, Sept. 27th.

DUBLIN.

(*From our own Correspondent.*)

QUEEN'S COLLEGE, CORK: ANNUAL REPORT.

THE President in his recent report alludes to the anarchy which pervades the whole educational system in this country. There are no longer any grammar schools; they have all become colleges. These colleges are curious, combining the functions of all the educational institutions, from a "Kindergarten" or infant school to a university college, inclusive. The result of this singular state of things, viewed from a statisticial point of view, is remarkable. The President believes there are more schools for "higher education" (university colleges, colleges, collegiate and university schools, collegiate schools, &c.) in Ireland, with a population somewhat over five millions, than in Germany, with more than forty millions of inhabitants. The Act of Parliament founding the Royal University of Ireland having opened its examinations, honours, and prizes to men and women alike, the College Council decided that the time had come to extend to women the full benefits of collegiate education, so as to enable those who desired to obtain University degrees to get the necessary teaching for the purpose. Five ladies entered, all of whom were matriculated students of the Royal University. They worked assiduously during the session, and all succeeded in passing the recent University examinations of their standing, three obtaining honours. Nothing has yet been done to enlarge the teaching staff at the College as proposed in the last two reports, but it is hoped that it will shortly be carried out. The President trusts also that the clinical teaching in the Cork hospitals will be reorganised, so as to combine the undoubtedly rich material for teaching which exists in Cork, and enable the College students to take full advantage of it.

SANITARY STATE OF NAAS.

Dr. Smyth, medical officer of Naas Union, has drawn the attention of the guardians to the insanitary condition of this thickly populated town. It contains about 521 houses, of which 98 have privies of the dangerous cesspit type, and 388 have no privies at all or any attempt at sanitary accommodation.

The salary attached to the curatorship of the Royal University has been fixed at £300 per annum, with an annual increase up to £400.

Dublin, Sept. 27th.

ROME.

(*From our own Correspondent.*)

THE wave of winter travel is now setting towards the Mediterranean, and Rome—thanks to the impending jubilee of Pope Leo XIII.—will receive more than her usual proportion of visitors. This increase in her foreign population (the English-speaking contingent alone has of late years averaged 30,000 during the season) makes her health a matter of supreme importance; but before touching on it, permit me to refer to a work just issued by her highest medical authority, Dr. James Moleschott, who, although of Teutonic parentage, has, now these thirty years, made Italy his home, having originally come to Turin at the instance of Count Cavour.

"Der Kreislauf des Lebens" (The Gyration of Life) is its title, and the edition just out is the fifth, recast up to date, in every department. When it first appeared (1852) it was a controversial treatise—a series of replies to Liebig's "Letters on Chemistry." Liebig was then at the zenith of his fame. His "Organic Chemistry in its Application to Agriculture and Physiology" and his "Letters on Chemistry" had made him accepted as an almost final authority, not only in academic circles, but in every factory and model farm in Europe. Young Moleschott, then *docent* in physiology and anthropology at Heidelberg, was also earning a name for himself as an investigator and expositor; and his "Physiologie der Nahrungsmittel," his "Physiologie des Stoffwechsels," his "Lehre der Nahrungsmittel," and, still more, his official prælections, had already attracted much attention in high places by their bold and trenchant criticism of scientific orthodoxy. Liebig was his main object of attack, and when he pronounced many of the great man's positions to be untenable, and even prejudicial to science, he drew down on himself the displeasure of the Government, and received the broadest of hints that his persistence in the line he had taken would be visited by the withdrawal of permission to teach in public. Moleschott took the hint very quietly, and went to Switzerland, having, however, bequeathed to Germany a controversy which did not cease till Liebig's too great authority had been reduced to juster and more salutary limits. Such was the origin of "Der Kreislauf des Lebens"; but what ground has not science covered between the first edition and the last! The Darwinian hypothesis, the discoveries and inventions in physics and chemistry, the newer physiology with its doctrine of nutrition revolutionised by Voit—all these "births of Time," as Bacon words it, find clear and telling exposition in these two volumes, of which the chapter on "Kraft und Stoff" (force and matter) would of itself suffice to fix its author's reputation as an original investigator and teacher. It more than justifies Cavour's sagacity in bringing Moleschott from Zurich to Turin to revive the languishing Piedmontese school, and it explains the signal advance made by Roman medicine during its author's ten years' professoriate at the Sapienza. The practitioners and health officers trained under such auspices cannot fail to render the city a much safer resort for the stranger, and, even in presence of an epidemic, to inspire a confidence not hitherto enjoyed within its gates.

As I write, the latest announcements from the statistical bureau represent the sanitary condition of Rome as maintaining the satisfactory position it has hitherto held compared with that of other European capitals. "Le condizioni sanitarie son buone assai," said to me a well-known practitioner this morning; and the weather with its delightful autumnal crispness, the water-supply abundant and pure to a degree that makes it the envy of all other cities, the activity of the "nettezza pubblica" and of the divisional health officers, all combine to give assurance of a safe as well as pleasant residence to the arrivals now

on the first day there was certainly more play than work. As usual at these sanitary congresses, the most insanitary conditions prevailed at the places of meeting. The want of ventilation was most apparent, the heat being very oppressive; and it is a question whether it would not be possible, at future congresses, to preach a little more by example, and provide properly ventilated rooms for the meetings.

Among the English present may be noted Sir Spencer Wells, Sir Douglas Galton, Dr. Cameron, M.P. (Glasgow), Professor Humphry (Cambridge), Professor Frankland, Professor Corfield (London), Dr. C. E. Rickard (Birmingham), Dr. Russell (medical officer of health, Glasgow), Mr. Shirley Murphy (London), Mr. Adolphe Smith (London).

On Tuesday morning the work of the Congress began in earnest. The different sections were crowded; many delegates were not able to obtain seats. The discussions proceeded in a very orderly manner, but some rather serious misunderstandings have already arisen through the confusion of tongues. A very important discussion, in which Professor Virchow and Professor Brouardel held different opinions on the dangers often present in drinking water, was brought to an unsatisfactory and premature close by the above cause. Next week it may be possible to disentangle the confused mass of speeches already delivered, and reproduce some of the more important arguments. For the moment it may be said, in conclusion, that the principal fault of the Congress is its overflowing success. The number of members now amounts to 2500; perhaps the figure of 3000 will be reached before the close of the proceedings.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE HOSPITAL SUNDAY FUND.

THE annual meeting of the Hospital Sunday Fund was held to-day, and the balance-sheet presented shows the full amount of the subscriptions and collections last year to have been £4044 11*s.* 1*d.* The balance carried from the previous year, with the interest added, makes a total of £404 0*s.* 10*d.* The expenses amounted to £307 12*s.* 8*d.*, and there was distributed to the various medical charities in all forms a sum of £3831 9*s.*, leaving a balance to be carried forward of £264 19*s.* 2*d.* The funds realised last year reached the largest total of any previous one, except 1883, which overtopped it by £81; but the church collections were slightly larger last year than in 1883, and reached the largest amount hitherto received. The workmen's collections, though not reaching the amount of 1883, realised, next to that year, the largest sum ever received. Altogether the report and the future prospects of the fund are highly satisfactory.

MEASLES IN NEWCASTLE.

The medical officer of health, Mr. H. E. Armstrong, has presented a report to the Sanitary Committee of the Corporation giving his reasons for recommending that measles should be included in the diseases to be notified by medical practitioners. He says it is the only disease which was severely fatal during last spring, and it is the only one not notified. He gives a table of the mortality from measles for the last seven years in Newcastle, which shows that in 1885 alone it caused 359 deaths, while in the first half of the present year (1887) the mortality has been 164.

MATCH-POISONING CASES.

The "match-poisoning craze," as it has been termed, still goes on in Newcastle. Several cass have been admitted to the infirmary since my last note on the subject, and they have for the most part recovered; but a fatal case took place there last week, when a married woman aged forty-nine succumbed to the effects of the poison. It appeared from the evidence given before the coroner that, after an unsuccessful attempt to destroy herself by hanging, she confessed to having dissolved the contents of six boxes of matches in a jug of water. She swallowed this and the usual symptoms of poisoning by phosphorus set in, causing her death in eight days, and after great suffering. It is sad to think that this poor woman committed suicide through being "back in her rent" and unable to obtain employment.

Newcastle-on-Tyne, Sept. 27th.

EDINBURGH.

(From our own Correspondent.)

THE NEW EXPERIMENTAL LABORATORIES.

I HAVE had frequent occasion to mention the laudable effort of the Royal College of Physicians of Edinburgh in the direction of increasing the facilities for experimental research in the Edinburgh School; and now that this effort is approaching a happy issue a few words are needed to describe the exact channel in which it has been directed. The idea originally conceived by some of the senior Fellows of the College, and more definitely formulated by an acting committee appointed for the purpose, was to construct a well-equipped centre at which any scientific question bearing on medicine might be practically worked out with as little inconvenience and delay for those engaged as could be obtained by the thorough organisation and efficient superintendence of the various departments of the institution. These desiderata have been obtained by a liberal expenditure of money and the appointment of a scientific man of recognised position to the post of superintendent. Dr. Woodhead has already obtained wide recognition as a valued worker in biology and pathology by his numerous contributions to medical literature; and he has now further emphasised his ability by the thorough manner in which he has superintended the difficult task of laboratory construction and equipment. Although the laboratory premises were not intrinsically well adapted to receive a school of experimenters, nor, in fact, particularly attractive buildings, yet their favourable position in close proximity to the infirmary and other centres of professional activity, and the satisfactory terms on which they could for a time be acquired, rendered their selection both necessary and politic. The site belongs to the managers of the Royal Infirmary, whose intention it is ultimately to replace the present old buildings by a commodious home for nurses; but until the time of that reconstruction they are glad to lease the premises for the useful purpose they now subserve. Although the exterior still retains the evidences of a century's wear and tear, a wonderful transformation has of late taken place within the buildings. Under the renovating influence of fresh paint, and the brightening effects produced by new fittings and the presence of well-kept scientific apparatus, the dingy old house has been converted into a series of light and airy laboratories, where there is every opportunity for carrying on scientific research. At a recent visit my attention was particularly attracted by the admirable equipment of the physiological experiment room. A water motor with extensive shaftings and couplings supplies power to recording apparatus in every part of the spacious chamber, so that a number of experiments can be performed simultaneously without danger of mutual inconvenience to the experimenters. In one part of the room stands a solid shaft of stone, passing through the floor, and founded on a firm basis of cement and stone, such as that employed for mounting equatorial telescopes. This massive shaft is to support a galvanometer, which is thus entirely isolated from the vibrations of the building in which it is placed. At one end of the room is the apparatus for carrying on artificial respiration, in thorough working order, and a good example of the workmanship turned out by the Cambridge Scientific Apparatus Society. Numerous glazed cupboards display a large assortment of recording drums, tambours, and the usual paraphernalia of such laboratories. In this department there is room for five or six physiologists to carry on their work without any overcrowding. A with chemistry room is in an advanced stage of preparation, stone counters, elaborate shelving, combustion chambers, and a number of ingenious fittings that will render work easy for the four experimentalists who can be accommodated here. An automatic still supplies this and the other departments with a perennial flow of distilled water. A separate balance room adjoins the chemical laboratory. One room is set apart for pathology and anatomy, in which is a collection of the most approved forms of microtomes and injecting apparatus. A special room is devoted to physiological chemistry, and two spacious well-lit rooms, each with two large dormer windows, are reserved for bacteriology and histology. The fittings in these rooms are convenient, and in some instances remarkably ingenious. In particular, I noticed the bell shades for covering the micro-

in sincerely thanking the president of your organisation committee, who has just addressed such kind words to me, I beg of you all to be assured that I consider it a pleasure and an honour to act as president of the Sixth International Congress for Hygiene and Demography. Man is the most precious capital of the State and of society in general. Every individual life represents a certain value. To preserve this as intact as possible to its furthest limit is not only a command of humanity, but also the duty of every community in its own interest. Whatever means may be at our disposal to protect our own individual welfare, left to ourselves we are powerless in face of the general injurious influences with which nature surrounds us on all sides. Here only common action can be of any avail, and this great task is undertaken by hygiene, supported by demography. It is hygiene based on a scientific basis which enables legislation to obtain practical results on the extensive field of health administration. Looking over the papers which will be read at this Congress, we recognise with astonishment that the science of which you, gentlemen, are such devoted disciples comprises every phase of social life—the dwelling-house and the school, production and war, the city and the village, trade and industry. The truly international importance of hygiene is also proved by the fact that so many illustrious representatives of all nations and countries are taking part in to-day's proceedings. I feel the greatest satisfaction, gentlemen, in welcoming you in this town, which is a centre of active scientific work and earnest research. In the name of His Imperial and Royal Apostolic Majesty, my most gracious master, I hereby declare the Sixth International Congress for Hygiene and Demography open."

Professor von Gruber, secretary of the Congress, spoke at length in German, but gave the conclusions of his speech in French. The Congress had departed a little from its original programme so as to allow Professors Brouardel and Pettenkofer an opportunity of delivering their addresses in the presence of the Crown Prince. In organising the Congress, the difficulty of the diverse languages had been in part overcome by publishing the opening papers in more than one tongue; for these papers they had appealed to distinguished specialists of all nations; and, thanks to the generous support given, the Congress possessed undoubtedly a truly international—indeed, a universal—character. The local committees in all countries had nobly helped the work; but more particularly were thanks due to the local committees of Buda-Pesth, of Berlin, of Paris and its Society of Public Medicine and Professional Hygiene, and of Belgium, and Holland. The programme of our labours, continued the Professor, has given us a day of rest, and we will profit by this to visit the institutions, old and new, of the capital. It will then be found that Vienna has many establishments built with a view to preserving the public health. The Municipality of Vienna would receive the members of the Congress at the Town Hall in the afternoon, and the Emperor himself had eagerly availed himself of the opportunity to show the interest his Majesty takes in the young science by conferring on the members of the Congress the high honour of a Court reception.

After a few words from Dr. Köhler, the Reichsgesundheitsammt of Berlin, Professor Brouardel of Paris was called upon to read the first paper, on the Propagation of Typhoid Fever. Speaking with the easy flow of language which distinguishes the eminent Professor, he tendered his homage to the Crown Prince, whom he was most pleased to see in the presidential chair. Sanitary science was not merely a subject of theoretic discourse. It must be followed by acts, and the Crown Prince was possessed of the power to act. His works also on science showed that he was further endowed with the knowledge which would enable him to know how to act. Professor Brouardel, though highly gratified, was not surprised at the excellent reception accorded to the Congress. Vienna for centuries was renowned for its hospitality to men of thought and study. Many had found in Vienna a second home. He would now seek to show what science had done; and, as an illustration, he selected typhoid instead of cholera, for in the long run it was the most fatal of the two diseases. At Geneva the International Congress was still undecided. Some said that typhoid arose from the fermentation of organic matter; others that a specific germ alone sufficed, without any decomposition of organic matter. The Congress could not agree whether the fever was contagious or only spread by water or the absorption, as food, of some other contaminated substance. In 1884 an effort was made to utilise the current of the Rhone as a motive power. A lock was constructed, and this caused some of the drinking water [illegible] to flow backwards towards the mouth of a sewer. [illegible] months previously this sewer received the dejections of two or three isolated cases of typhoid fever. In a few days after the contamination of the water supply a terrible epidemic broke out in Geneva, and there were no less than 500 cases. Last year at Clermont Ferrand and Mont Ferrand there were 300 cases of typhoid due to water contamination, while such places as Chamavière and Royat, though close by, escaped, their water being derived from a different source. In Paris, whenever the supply of the pure water from the Vannes or the Dhuys fell short, and the waters of the Seine, the Ourcq, or the Marne were used instead, the hospitals were filled with patients suffering from typhoid fever, precisely three weeks after such alteration in the character of the water supply. Studying the question from the bacteriological point of view, Dr. Brouardel showed that the multiplicity of microbes rendered this investigation very difficult. After five years it was found that a few drops of carbolic acid in a culture broth had the property of killing all these microbes with the exception of the special microbe of typhoid fever. This latter developed so slowly that it escaped the action of the acid. In the examination of the waters the same process was used; and now it was possible to say definitely that such or such a substance contained the real germ of typhoid. At the same time he was not prepared to say that typhoid could never arise merely from foul air. In a family of nine, living on identically the same food, a son alone contracted typhoid fever. It was found that under his room window there was an open soil pipe. In another family precisely the same incident occurred, and this among his own patients, and quite recently. Nevertheless water was the more general cause of the disease. He concluded by urging that it was more easy to cover water than to protect open rivers or canals from contamination. Water ought to be brought to the large towns in pipes or closed aqueducts. If we thus protected the health of the great centres, the rural districts would also largely benefit, as their epidemics were very often imported from towns. Dr. Brouardel concluded amid cordial applause.

Herr von Pettenkofer then read the second paper, on the Teaching of Hygiene in the Public Schools and Universities. Practical hygiene was the precursor of scientific hygiene. A rough conception of the agreeable and the disagreeable had in the first instance guided humanity. From this premiss scientific hygiene had developed. Practical hygiene is as old as humanity itself. What Englishmen call "comfort" is based on hygienic law. In the seventh century, when London had not a million inhabitants, the mean mortality was 42 per 1000 per annum; while now, with a population of 4,000,000, it is less than 21 per 1000. This sprang from the due observance of the British maxim that cleanliness is next to godliness. The professor then discussed at length the financial economy realised by the preservation of public health. In war even, disease more than the enemies' bullets killed the greater number of soldiers. But the Crimean war was particularly fruitful in showing how hygiene could and must be introduced into the army medical schools. Other States are now following the English example. In the Franco-German war the result of this teaching could already be perceived. Thus the whole loss of the German army was 40,881: killed in battle 28,282, accidents 346, and disease 12,282. In the Crimean war the French lost a third of their whole army, 95,000 men. Only 20,000 out of this number were killed, while 75,000 died from disease. Many further and most conclusive tables were given setting forth the saving of life and money that had rewarded the spread of education, and a better knowledge of the influence of air, water, and soil on the public health. He urged the necessity of establishing special schools for experiments, as on experiment alone could the laws of hygiene be established.

After this speech, which had been warmly received, the meeting broke up, and some of the prominent members of the Congress were introduced to the Crown Prince.

On Tuesday the reception given by the municipality at the magnificent Town Hall of Vienna was a most brilliant success. The Town Hall was effectively illuminated, a sumptuous repast with many Viennese delicacies was provided by the municipality, and an excellent band played in the large hall. Later in the evening a more social entertainment (*Kneipabend*) was organised, consisting of a simple supper, with music, choruses, and solo songs. Thus

Digitized by Google

practitioner; that it induces the relatives of the sick, knowing what will follow upon notification, to hesitate to call in timely medical assistance, and to conceal the existence of infectious disease, and thus to do an injury to the patient in the first instance, and in the second to contribute to the unsuspected extension of infection throughout the community. That the medical profession in Bolton therefore emphatically condemn compulsory notification by the medical practitioner as being contrary to the public advantage."

I am, Sirs, yours &c.,

Bolton, Sept. 24th, 1887. NORMAN MCLIESH, M.A., M.B.

HUGHES *v.* LANGMORE.

To the Editors of THE LANCET.

SIRS,—May I ask to be allowed space in your columns to thank briefly, but heartily, those members of the profession—over a hundred in number, and many of them strangers to me—who have so kindly relieved me of about two-thirds of the heavy expense to which I became liable in consequence of the action brought against me by a patient whom I had been compelled, and as the verdict of the jury showed, not without reason, to certify as insane. Although one would rather not throw away £80 or £90 in defending an action of this kind, still that is within the amount (£100) which I was told from the first the case would cost me, and the loss of which I had come to look upon as inevitable. The actual cost (£250) was, I must confess, an exceedingly unpleasant addition to the trouble and worry I had already undergone, and I am very grateful to the friends and fellow practitioners by whose kind assistance it has been so largely reduced. I am, Sirs, yours gratefully,

J. WREFORD LANGMORE.

Oxford-terrace, Hyde-park, Sept. 26th, 1887.

VOLUNTEER MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Will you allow us, through the medium of your journal, to call the attention of Volunteer medical officers to the circular letter and form of membership which were recently forwarded to them, and to ask them to fill the membership form up and forward it to us without delay. The appeal of the Council has been remarkably successful, and we are happy to say the success of the movement is now fully assured, but the Council are very anxious to secure the co-operation of as many Volunteer medical officers as possible, and they feel that possibly their letter may have been mislaid in the case of some who were absent from home. The Council have it in contemplation to invite the President, H.R.H. the Prince of Wales, to preside at the first meeting of the Volunteer medical officers mess, and we are expressly requested to invite any Volunteer surgeon to apply to the office for any information he may require, and in every way to avail himself of the privilege now offered by the Association.

We are, Sirs, yours faithfully,

JAMES CANTLIE, ALFRED LINGARD, } Hon. Secs.

26, King William-street, Strand, W.C., Sept. 28th, 1887.

THE SIXTH INTERNATIONAL CONGRESS OF HYGIENE.

(From our Special Correspondent.)

IT is impossible to avoid the impression on reaching Vienna that the Congress is in some danger of being paralysed by its own extraordinary success. Never before has such a gathering been so well supported. No less than 2400 persons have paid their subscription of the ten florins each and enrolled themselves as members of the Congress. Nor is it mere abstract support; the majority are present in person, and it has been no easy matter to house so vast a throng. This difficulty is now overcome. Some of the delegates have been compelled to content themselves with very humble quarters, but this trifling inconvenience has to be endured on such occasions. What is more serious is the management of the Congress itself. In this respect it is to be feared a mistake has been committed. Though reports have been printed, introducing no less than twenty-two subjects for discussion, the Congress will be divided into only three sections. Nor is this all. The Sections will not meet on Monday, and Thursday will be given up entirely to an excursion to the mountains, which are the source of the Vienna water supply. There are, therefore, only four days given to more than 2200 people to discuss twenty-two subjects. Evidently many a delegate will have to return home with his speech unspoken.

Before the opening of the Congress—that is to say, on Sunday evening—the festivities which this town is organising on a lavish scale already commenced. Several hundred delegates assembled in the best rooms of the Horticultural Society, situated in the Park ring, which is the boulevard of Vienna. A sumptuous supper was provided, including some Danubian fish, which was highly appreciated. There were no speeches, as the evening was intended as an opportunity for renewing old acquaintances and making new ones. Already rumours are floating about as to the place to be selected for the next Congress. The Russian delegates are authorised to invite the Congress to St. Petersburg; but this is considered a long and expensive journey, to say nothing of the prospect of Siberia if some of the delegates speak too freely. The Society of the British Medical Officers of Health and the British Sanitary Institute have agreed to invite the Congress to London. Assuredly this is only right, and England should before now have taken the initiative. Unfortunately, the British Government affords no assistance whatever. The pettiest countries of Europe, as well as all the great Powers, have their official delegates present at this Congress; but the few Englishmen who are here come on their own account, at their own expense, or as the representatives of societies that are the outcome of private endeavour and receive no support from the State. Certainly this is felt keenly by our continental colleagues; and many express wonder that England, which has done so much for the health of its own people, should in no wise have contributed to spread the knowledge of sanitary science in other countries. The fact that England is at last moving and will invite the Congress to meet in London will be taken as an awakening, and is sure to meet with much approval. But there is a third and still more likely proposal—that is, to hold the Congress in Paris during the great exhibition of 1889. Everyone will then desire to be in Paris; and frequenters of these congresses will remember the great success of the second International Congress of Hygiene which met in Paris precisely under similar circumstances—that is, during the Universal Exhibition of 1878. It is doubtful also if the English would, in the main, care in any way to mar the great rejoicings which are organised to celebrate the centenary of the advent of freedom in France.

At 10 o'clock on Monday morning the beautiful hall of the Friends of Music was already thronged by delegates in the body of the building, and by a fashionable and elegant crowd of ladies and gentlemen in the gallery. On the platform the brilliant uniforms of Austrian officers, and the rich decorations and ribbons that decorated the breasts of the foreign official delegates made up an impressive picture. With military punctuality the Crown Prince Rudolph marched up to the platform amid the "hochs" of the assembly, and the proceedings immediately commenced.

Dr. Ernest Ludwig, Professor of Chemistry at the Vienna University, advanced to the side of the platform, and, bowing to the Prince, explained that from all parts of the civilised world men of science had gathered in Vienna. The Governments of nearly all the great Powers and the municipalities of many celebrated towns had their official representative standing close around the Prince. Never before had such a large and distinguished number of delegates met together to advocate the cause of sanitary science. This was a proof that the importance of hygiene was more widely recognised. Such progress was natural, for thus science would dispel most of the social evils from which we suffer. It was a promising feature of our modern civilisation to see so many nations working harmoniously together in the advancement of their common interests. Then, after describing the general scope of the meeting, Professor Ludwig declared that all was ready, and that they were only waiting for the Crown Prince to open the Congress.

The Imperial Prince at once rose and said: "Gentlemen

Digitized by Google

which may suffice to explain why a self-limited morbid action excited by a germ should end, but not why the product of such activity should protect against a recurrence. Should it point to the possibility of counteracting a poison already received? Such view is stated in the most able and valuable report of the Hydrophobia Commission to be both novel and wanting proof. I agree with the report except as to the estimate of death to bites; a much smaller proportion than that adopted by the eminent members of the commission recommends itself to me. But the report is in accord with the popular voice—"Victrix causa Diis placuit, sed victa Catoni." I am, Sirs, yours truly,

Sept. 26th, 1887. WILLIAM SQUIRE, M.D.

TREATMENT OF CANCER BY THE ADMINISTRATION OF LIME.

To the Editors of THE LANCET.

SIRS,—Since the appearance in THE LANCET (May 7th, vol. i. 1887, page 927) of the communication therein inserted relative to the administration of lime as a proposed cure for cancer, in which the powder obtained from oyster shells was recommended, I have received numerous letters from medical men and others asking me for more detailed information on the subject. It has occurred to me that I could not more readily supply this information than by requesting the favour of you to publish the following observations. Instead of carrying out to the letter the advice recommended of obtaining the carbonate of lime from oyster shells by baking them in an oven, which is not only a troublesome process, but at certain seasons of the year difficult, when oysters are out of season, I advise (what is analogous to it) the oyster preparation of the London Pharmacopœia. Six grains of this may be taken twice or three times a day in a wineglassful of milk or other fluid, such as tea.

With reference to the application of an ointment containing lime mixed with perfectly fresh butter devoid of salt to an open cancer, I find that the smell of the butter is objectionable, and when cream has been substituted the objection to it is that it so hardens the lime that it is difficult to remove it from the sores. Instead, therefore, of using either one or the other of these, I recommend the following ointment:—Creta preparata, three drachms; ol. amygdal., two drachms; the lime to be intimately mixed with the oil, and then to be added two ounces of lanoline; this to be applied twice a day spread on lint. Should the smell of this ointment prove disagreeable, it may be counteracted by adding three or four drops either of essence of bergamot or oil of geranium. I find that the employment of lime for the purpose of curing cancer does not prohibit the use of other drugs that the patient may require. I am, Sirs, yours obediently,

P. HOOD, M.D.

Seymour-street, Portman-square, Sept. 1887.

SEWERS IN INDIA.

To the Editors of THE LANCET.

SIRS,—Sanitarians owe a debt of gratitude to Dr. Vivian Poore for his able *exposé* of the dangers of horizontal cesspools. In India vast sums of money have during the past few years been expended in introducing systems of sewerage into Calcutta, Bombay, and Lahore. Now, two equally, in my opinion, disastrous schemes are being put forward for Karachi and Hyderabad, Sinde; and Allahabad, Lucknow, and Agra keep nibbling at them like specious baits. As a consequence of the Calcutta sewerage, epidemics of enteric fever have been notoriously prevalent during recent years, and the cholera last November was the most severe that has occurred in any year since the introduction of an incompletely distributed water supply in 1870. As regards this cholera, it must, however, be remembered that tanks and other objectionable sources of drinking water in and about groups of huts *(bustis)* in the town and suburbs have not been completely eliminated, as Dr. Simpson's report on the localised outbreak on the ship *Ardenclutha* shows. The water supply is consequently still very defective. An extraordinary and fatal fallacy is disseminated by engineers in India, to the effect that in no country is the problem of sewer ventilation so simple, because the outside air being warmer than the air inside houses, there is little fear of sewer air being drawn into houses, as in England. I believe the truth is that in no country is the problem so difficult a one. In the hot weather, when the air is often perfectly stagnant for many hours, or even days, there is no perflation, the highly heated external air (thermometer, minimum in shade 115°, maximum 170°) is much lighter than the cooler sewer air, forced out by flushing and other means through the sewer "ventilating" shafts. Consequently sewer air, not diffused into the upper strata of the atmosphere and blown away by the wind as in England, falls as a disease-bearing shower towards the ground, and by its gravity occupies the lower or respiratory stratum under seven feet from the ground, poisoning the air breathed by the unfortunate tax-payer.

In the town of Mirzapur (N.W.P.) there were old sewers, not even supplied with ample flushing apparatus to force out the sewer gas into the narrow streets and alleys, yet on a hot still day the effluvium as one passes along the streets in the evening is sickening in the extreme. Forcing out foul gases, which must be rapidly generated in a hot climate, by flushing would only make things worse. The only perfect remedy is to fill up the sewers and to take to the Goux or some other similar pail system. The fact that impure air expired at a temperature of 100° F. (as also sewer air from underground sewers) is cooler than the surrounding and superjacent air in a barrack at night, when the temperature of the building is 106° or more, to my mind offers a full, simple, and sufficient explanation of the fact that heat-stroke often attacks people in bed at night. When in the horizontal position only the four feet of air nearest the floor are practically available for respiratory purposes. Hence the great importance of ample superficial space (150 sq. ft. as a minimum) compared with cubic space.

The issue of your report on the Manchester pail system, Aug. 6th, p. 280, is most opportune. As an avowed opponent of sewers, I earnestly recommend all interested in sanitation in India to study Dr. Poore's lecture and the Manchester report.—I am, Sirs, yours faithfully,

SHIRLEY DEAKIN, M.S., S.Sc. Cert. Camb.,
Surgeon-Major.

THE COMPULSORY NOTIFICATION OF DISEASE.

To the Editors of THE LANCET.

SIRS,—Speaking of an Act for the compulsory notification of infectious disease, Lord Basing says, "I am happy to state that such an Act is in force in Bolton and works well." His lordship has been founding his remarks on *ex parte* statements. It must have struck anyone acquainted with the town that very few of the local medical men have taken part in the proceedings. The acts and sayings of such a Congress as that now sitting in Bolton will probably have great weight in Parliamentary circles, and may even be made the basis of subsequent legislation. For this reason the medical men of Bolton are unwilling that misleading statements should go abroad to the effect that they acquiesce in the Act for the compulsory notification of disease by medical men. They do not object to compulsory notification by the householders, but they do think that it is a gross injustice to place the responsibility of notification coupled with a heavy pecuniary fine upon them. The medical men of Bolton do not think the Act "works well"; they think it causes friction all round. With a view to express their feelings a meeting was recently held, which was attended by half the medical men of the town, and I am sure that I am within the mark when I say that the result of that meeting will be endorsed by 90 per cent. of the remainder. The meeting deemed it courteous first to send a copy of the resolution to the secretary of the Sanitary Institute, in order that that body might afford to the medical men of Bolton some special opportunity of speaking for themselves. The meeting appointed a committee to watch the matter, and authorised it, if no notice was taken of the resolution, to take steps to bring the resolution before the public. No reply having been received to their communication, the committee have instructed me to publish the resolution in the local papers and in the medical journals. I subjoin the terms of the resolution.

Resolved:—"That the medical practitioners in Bolton are of opinion that compulsory notification by the practitioners disturbs the confidential relations between patient and

Digitized by Google

diseases in the twenty-eight towns, which had declined in the preceding eight weeks from 1301 to 624, further fell last week to 440; they included 185 from diarrhœa, 72 from scarlet fever, 61 from whooping-cough, 54 from "fever" (principally enteric), 35 from diphtheria, 29 from measles, and only 4 from small-pox. These zymotic diseases caused the lowest death-rates last week in Bolton, Huddersfield, and Halifax; and the highest rates in Manchester, Hull, Blackburn, and Salford. The greatest mortality from diarrhœa was recorded in Blackburn, Salford, and Hull; from scarlet fever in Manchester, Blackburn, Bristol, and Birkenhead; from measles in Oldham; from whooping-cough in Nottingham; and from "fever" in Brighton, Salford, Portsmouth, and Nottingham. Of the 35 deaths from diphtheria in the twenty-eight towns, 21 occurred in London, 3 in Oldham, 2 in Birmingham, 2 in Liverpool, and 2 in Manchester. Small-pox caused 4 deaths in Sheffield, but not one in Greater London or in any of the twenty-six other large towns. Only 4 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; whereas the number of cases of scarlet fever in the Metropolitan Asylums Board hospitals and in the London Fever Hospital had increased to 1481. The deaths referred to diseases of the respiratory organs in London, which had been 169, 160, and 142 in the preceding three weeks, rose again last week to 160, but were 41 below the corrected average. The causes of 56, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Leeds, Salford, Leicester, and in three other smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Hull, Cardiff, and Portsmouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 and 18·7 per 1000 in the preceding two weeks, further declined in the week ending September 24th to 18·3; this rate exceeded, however, by 2·1 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·7 and 12·2 in Perth and Leith, to 25·4 in Greenock and 25·6 in Paisley. The 457 deaths in the eight towns last week showed a further decline of 10 from the numbers in the previous two weeks, and included 28 which were referred to diarrhœa, 22 to whooping-cough, 11 to "fever" (typhus, enteric, or simple), 11 to scarlet fever, 5 to diphtheria, 1 to measles, and not one to small-pox; in all, 78 deaths resulted from these principal zymotic diseases, against 112 and 106 in the preceding two weeks. These 78 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·6 the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 39, 45, and 55 in the previous three weeks, declined last week to 28, of which 10 occurred in Glasgow and 7 in Dundee. The 22 deaths from whooping-cough showed an increase of 3 upon the number in the previous week, and included 7 in Dundee, 4 in Glasgow, 4 in Edinburgh, and 4 in Greenock. The 11 deaths referred to "fever" corresponded with the number in the previous week; 6 were returned in Glasgow and 5 in Paisley. The fatal cases of scarlet fever, which had been 11 and 17 in the preceding two weeks, declined again last week to 11, of which 5 occurred in Glasgow and 5 in Dundee. Three of the five deaths from diphtheria were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 71, 66, and 77 in the preceding three weeks, declined again last week to 62, and were 3 below the number returned in the corresponding week of last year. The causes of 58, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·9 and 34·3 per 1000 in the preceding two weeks, declined again to 30·6 in the week ending September 24th. During the first twelve weeks of the current quarter the death-rate in the city averaged 31·0 per 1000, the mean rate during the same period being but 20·0 in London and 18·3 in Edinburgh. The 207 deaths in Dublin last week showed a decline of 25 from the number returned in the preceding week; they included 37 which were referred to diarrhœa, 8 to measles, 4 to scarlet fever, 1 to "fever" (typhus, enteric, or simple), 1 to diphtheria, 1 to whooping-cough, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 77 and 52 in the preceding three weeks, were again last week 52; they were equal to an annual rate of 7·7 per 1000, the rate from the same diseases being but 2·1 in London and 1·6 in Edinburgh. The fatal cases of diarrhœa, which had been 36 and 35 in the previous two weeks, rose last week to 37, and exceeded the number in any week since the middle of August. The deaths from scarlet fever showed an increase of 2, while those from measles corresponded with the number in the previous week. The deaths of infants showed a marked decline from recent weekly numbers, while those of elderly persons had slightly increased. Two inquest cases and 2 deaths from violence were registered; and 53, or more than a quarter, of the deaths occurred in public institutions. The causes of 35, or nearly 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

THE Greenwich Hospital Pension of £50 a year for Fleet and Staff Surgeons, R.N., vacant by the death of Deputy Inspector-General James Vaughan, has been awarded to Deputy Inspector-General George Moore, M.D.

WAR OFFICE. — Army Medical Staff: Surgeon-Major Edmund Farrington Boult, half pay, is granted retired pay, with the honorary rank of Brigade Surgeon (dated Sept. 24th, 1887); Surgeon-Major Frederick William Lloyd Hodder, M.B., to be granted retired pay, with the honorary rank of Brigade Surgeon (dated Oct. 1st, 1887).

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon R. C. Widdicombe, to the *Prince Albert* (dated Sept. 11th, 1887); Surgeon William Prior, to the *Sphinx*; Surgeon John Menary, to the *Neptune*; Surgeon Alexander W. M'Leod, to Haslar Hospital; and Surgeon James A. Vassey, to the *Duncan* (dated Sept. 26th, 1887).

Correspondence.

"Audi alteram partem."

PROTECTIVE POWER OF VACCINATION.

To the Editors of THE LANCET.

SIRS,—The experience your correspondent, Dr. Hugh Thomson, questions is recorded in the reports of the London Asylums Board's hospitals. In one case of mistaken diagnosis received into a small-pox ward, vaccination on entry failed to ward off an attack. There are several instances in the earlier reports of nurses having contracted small-pox when vaccinated at the time of entry upon their duties, not one when the vaccination preceded the engagement. Many cases of this kind escape record. During the past London epidemic a tramp reached Ampthill Workhouse with bad small-pox; an inmate told off to attend upon the sick man was at once vaccinated, but took small-pox in a severe form. Cases of concurrent variola and vaccinia are not rare; one such has appeared recently.

Though I enjoyed the advantage of intimate converse with the late Mr. Marson, I am unable to say which of the two theories mentioned he favoured. I know that he trusted to neither of them in practice, and never received anyone for duty in small-pox wards immediately upon vaccination, but waited for the result to be evident, and even advanced to the stage of areola, before engaging servant or nurse. Men of genius like Marson and Pasteur, with large experience in a special subject, require a theory as an aid in further work or a goal or object first. Marson's use of his theory was to favour the practice of vaccinating all those in any house or room where small-pox happened. The frequent success of this practice may be urged in support of a view I do not share. It is a good illustration of that for which I contend—viz., how frequently those exposed to infection escape. The masterly researches of M. Pasteur into zymotic processes have inclined him to adopt a new theory, one

Supervision of Cowsheds, Dairies, and Milkshops," and by Mr. E. W. Hope on "Localised Outbreaks of Typhus Fever and Infantile Diarrhœa."

The Conference then concluded.

THE CONGRESS OF GERMAN PHYSICIANS AND NATURALISTS AT WEISBADEN.

Of all the addresses delivered at this gathering, which closed on the 22nd ult., Professor Virchow's proved the most memorable, and its publication will be awaited with much interest in the scientific world. Its subject was "Transformismus." Its tenour may be inferred from the following brief indications. The law of heredity, in spite of all reservations, must be admitted to be universally shared by all beings endowed with life—a law on which, beyond doubt, depends the continued existence of the living world. But science will always yearn to know how life, as a whole, has originated, though attempts to satisfy this longing through the dogma of the eternity of the living world have hitherto invariably broken down. There remain only the dogma of creation and the dogma of self-production (*Urzeugung*). Neither of these can be an object of research, for never yet has a living being, or even only a living element, been found of which it could be said, "This is the first of its kind." Professor Virchow proceeded to show that from whatever point the question is approached it invariably eludes the grasp. He announced himself as the friend, not the opponent, of transformism—as having at all times approached the "immortal Darwin" not aggressively, but amicably. He has always, however, observed a practical distinction between the friend and the follower. As a friend he could welcome and support a scientific hypothesis even before it has established its truth by facts; but until these are forthcoming and conclusive he could never fall into the ranks as a follower. Whoever, he said, can teach us how to grow a "Spaltpilz" out of a "Schimmel-pilz" will have achieved more than all the heralds of the genealogical tree of man.

Among the other papers of most interest to the physician were those of Dr. Meiner of Dresden on the Influence of the Atmospheric Temperature on Infantile Diarrhœa; of Herr Wollmar, an apothecary (also of Dresden), on the Rational Disinfection of Latrines; of Dr. Poehl of St. Petersburg, on the Chemical Properties of Water and their Relation to the Life-activity of Micro-organisms; of Dr. Gerlach of Biebrich, on Peptones; of Dr. Bockhardt of Wiesbaden, on a New Preparation for furnishing a Stable Nidus for the Culture of Micro-organisms; and of Dr. Lender of Berlin, on Medical Climatology considered in Relation to the Treatment of Malaria (an admirable bit of exposition). Professor W. Detmer's paper on Plant Life and Plant Respiration was among the most esteemed of the non-medical contributions. Before the Congress rose Cologne was approved as its next place of meeting, when Professor Virchow's suggestions as to certain fundamental alterations in the statutes will be discussed. Heidelberg was proposed for the Congress of 1889, but this was left open to change.

BRITISH MEDICAL BENEVOLENT FUND.

The first monthly meeting of the committee of this Fund after the vacation was held on Tuesday last, and a long list of cases, the accumulation of two months, was submitted. They numbered twenty-four, eight being first applications, and were disposed of as follows:—Grants of from £5 to £18 were made to eighteen applicants; one had died, aged eighty, since her application was received; five were postponed for further information or informality; and one application was refused. In one instance the sum of £10 was offered by the committee on condition that a subscription of £50 was raised on behalf of a member of the profession, aged seventy-one, and hopelessly paralysed. A sum of £200 in all was voted, and the balance at the disposal of the committee entirely used up. Such a position for so useful a charity is very deplorable, and the committee venture to appeal to those members of the profession who possess the means to assist them by sending subscriptions at once to the treasurer or any of the officers of the Fund, by whom they will be most thankfully acknowledged. The later months of the year are always the worst for getting in subscriptions, and the committee find that the cases which come before them at that time are generally worse in character, to add to the additional reason for more liberal grants in the winter season. As a rule, the committee order the grants to be paid in monthly instalments, thus spreading the benefit of the assistance over as long a period as possible, and ensuring the utmost value for the donations of subscribers. During this year 110 applicants have already been relieved by the donation department at a cost of £1533.

ROYAL SOCIETY.

At a recent meeting of the Society, Mr. Victor Horsley, communicated a paper by Mr. G. F. Dowdeswell, M.A., on Rabies, of which the following is an abstract:—

In this investigation conducted in the laboratory of the Brown Institution, commenced early in 1885 during the outbreak of rabies in London, the first experiments, made by subcutaneous inoculations with the saliva of rabid street dogs, all failed to produce infection. Subsequently, adopting the methods described by M. Pasteur, Mr. Dowdeswell found—1. That the virus of rabies and hydrophobia resides in the cerebro-spinal substance and in the peripheral nerves, and is not confined to the salivary glands, as hitherto supposed. 2. That by inoculation of this substance upon the brain of another animal by trephining, infection follows much more quickly and certainly than by subcutaneous inoculation. 3. That rabies, however produced, in both dogs and rabbits, is essentially a paralytic affection, the same disease in both animals, and that there is no constant distinction between the so-termed "dumb" and "furious" rabies. 4. That the initial virulence of street rabies is usually increased, and becomes remarkably constant, by passing through a series of rabbits. 5. That the activity of the virus is shown by the duration of the incubation period, to which it is inversely proportionate. 6. That the tissues of an infected animal do not themselves become infective till towards the end of the incubation period. 7. That of a large number of drugs that were tried, both germicides and those acting specifically upon the cerebro-spinal system, none materially modify the action of the virus in the rabbit. 8. That by a series of subcutaneous inoculations with virus treated by the methods of M. Pasteur, immunity, even against subsequent infection, cannot be conferred upon the rabbit; and that the extreme and unexpected constitutional refractoriness of the dog to infection with rabies by any method of inoculation—as the author found it in the limited number of experiments he had been able to perform with this animal—renders it extremely difficult to determine the effect of such remedial or prophylactic measures in it; and that it is by the statistics of the treatment alone that their effect with man can be decided; but that, judging from the results of the experiments of others, the principle of the method as affirmed by M. Pasteur appears to be established, though unquestionably the "rapid" or "intensive" treatment, as Mr. Dowdeswell had found, is liable to produce infection.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5706 births and 2872 deaths were registered during the week ending September 24th. The annual rate of mortality in these towns, which had steadily declined in the preceding six weeks from 23·7 to 18·0, further fell last week to 16·2, and was lower than the rate in any week since the end of September, 1885. During the first twelve weeks of the current quarter the death-rate in these towns averaged 20·7 per 1000, and was 0·3 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 10·0 in Derby, 10·7 in Bolton, 13·5 in Nottingham, 13·8 in Leicester, and 14·4 in London. The rates in the other towns ranged upwards to 20·9 in Newcastle-upon-Tyne, 22·5 in Sunderland, 23·5 in Manchester, and 26·4 in Blackburn. The deaths referred to the principal zymotic

Digitized by Google

A POST-GRADUATE course of lectures will commence at Charing-cross Hospital on Friday, Oct. 7th, at 3 30 P.M., when the opening lecture will be delivered in the Board-room of the hospital by Dr. Julius Pollock, the senior physician, the subject being "Rheumatism." The lectures will, we are informed, be eminently practical and illustrated by cases in the wards, the staff of the hospital will assist in the clinical demonstrations, and the instruments, appliances, &c., necessary for illustration at each lecture will be on the table for the inspection of the class. All qualified practitioners may join, and the day and hour (Friday, at 3.30 P.M.) seem to be chosen as the most convenient to medical men in general practice.

IN the approaching winter session Dr. Mercier will deliver at the Westminster Hospital Medical School a course of lectures on Neurology and Alienism. The course, which will be post-graduate in character, will include a review of the general functions of the nervous system, setting forth the nature and varieties of coördination, inhibition, &c., an account of the manner in which conduct is affected by the action of the higher nerve centres, and a description of the ways in which the mind may become disordered. The lectures will take place at 4 o'clock on Friday afternoons from October to Christmas.

FRANCIS OGSTON, LL.D. Aber., M.D. Edin., late Emeritus Professor of Medical Jurisprudence in the Aberdeen University, died on the night of Sept. 25th. He was eighty-five years of age, and retired from his professional duties some four years ago. In addition to his important "Lectures on Medical Jurisprudence," he was the author of numerous papers in medical journals, both English and German.

A MEETING of divisional surgeons of the Metropolitan Police was held on Thursday last at 429, Strand, Mr. T. Bond in the chair, to take steps to found a "Police Surgeons' Association." A further meeting will be held in November, to receive a report of the provisional committee, and to discuss the formation of rules, &c.

STAFF-SURGEON PEARSON, R.N., M.D., who, having been taken very ill, was recently landed at Gibraltar by the corvette *Thalia*, died on Saturday, September 24th.

MR. CASSAL has resigned his appointment as Demonstrator in the Hygienic Laboratory of University College, London.

IT is now denied that Dr. Neusser has given up his appointment with Prince Ferdinand of Bulgaria.

SANITARY INSTITUTE OF GREAT BRITAIN.

AT the sitting of this Conference on the 22nd ult, the address to Section II. (Engineering and Architecture) was read by Professor T. Hayter Lewis, F.R.I.B.A., who took for his theme the extension of our great cities and the erection of new ones, his object being to ensure that such requirements as were now considered to be necessary for their healthful occupation might be provided for at the outset.

A paper was afterwards read on the "Fouling of Streams" by Major Flower, sanitary engineer to the Lea Conservancy Board.

Other papers were read—by Mr. J. J. Bradshaw on "The Sanitary Condition of Cotton Factories"; by Mr. S. H. Merry on "The Water Supply of Villages"; and by Mr. R. Sutcliffe on "Artesian Wells and Water Supply."

A conference of medical officers of health was also held during the morning.

Lord Basing, in a brief opening address, said the conduct of public health was rapidly passing from the central office to the localities, and it was through the effective intervention of medical officers that rapid progress in the cause which they had at heart became probable.

Professor Corfield, President of the Conference, then took the chair.

A paper on "Death Causes and their Classification" was read by Mr. Vacher of Birkenhead, in which he urged that in every case of death the cause of it should be medically certificated. In the discussion which ensued, Lord Basing, Dr. Carpenter, Mr. North, Dr. Sykes, Dr. Tatham, Mr. Armstrong, and others took part. Dr. Carpenter said the question of coroners' courts should be dealt with in the Local Government Bill which was to be brought before the country. He was prepared to support a proposal that the coroner should have at his command the services of a thoroughly educated medical practitioner as assessor. He thought it would be greatly to the interest of science to get a very much more simple nomenclature of disease than that issued by the Royal College of Physicians. Dr. Sykes advocated more accurate certification in order to get better classification. The following resolution was afterwards unanimously adopted: "That in the opinion of this meeting it is desirable that the medical officer of health should act in the capacity of assessor to the coroner in all cases of death in which there has been no medical attendant, or none from whom a certificate of death can be obtained; and that in such capacity it should be the duty of the medical officer of health to make full inquiry into all cases of suspicious or uncertified death."

Papers were also contributed by Dr. Kenyon, of Chester, on "The Provision for Infectious Patients in Rural Districts," and by Dr. Stopford Taylor, of Liverpool, on "The Liverpool Port Sanitary Authority and its Work." The Conference then adjourned.

On the 23rd ult. two Sections sat. Papers were read in Section II. (Engineering and Architecture) by Mr. R. E. Middleton, M.I.C.E., on "House Drainage"; by Mr. J. Honeyman, F.R.I.B.A., on "The Proper Size of House Drains, and the use and misuse of Traps"; by Mr. J. Corbett, on "Health, Comfort, and Economy in Cottage Construction"; and by Messrs. H. Fletcher, D. J. R. Duncan, and O. D. Orvis, on "Smoke Abatement." In Section III. (Chemistry, Meteorology, and Geology), the papers for discussion were: "The Application of Bacteriology to Questions relating to Water Supply," by P. Frankland, Ph.D., F.C.S.; on "Water Analysis," by Louis Parkes, M.D.; on "The Sources of Hygienic Significance of the Impurities of the Air of Buildings and Sewers," by J. S. Haldane, M.A., M.D.; on "Underground Water Supplies," by C. E. De Rance, A.I C.E.; on "River Pollution in Lancashire," by J. Collins, F.C.S.; and "The Sanitation of Dwelling-houses, &c," by G. Selkirk Jones, L.S.A.

Dr. August Dupré, the President of the Chemistry and Geology Section, in an address to a general meeting of the members, said sanitary science was practically, as far as modern times were concerned, the growth of the last fifty years, and surely no advance in any science or industry had done more to help on the welfare of the people than the advance in sanitary science. He would content himself with two subjects of sanitary science on which he could claim some special knowledge—water and sewage, the two most important subjects on which the chemist could aid the sanitarian. He advocated the collection of water standards from various neighbourhoods as tests of purity or otherwise. On the question of sewage he expressed the belief that the water carriage of sewage was more or less a mistake, but they were committed to it and had to make the best of it. Every authority that had to deal with sewage should give up the idea of making a profit out of it. Unless the sewage was burned, he believed the ultimate destruction of that sewage was due to living organisms, and they must do nothing to hinder the action of those organisms, but do all they could to help them. It would be quite impossible to disinfect any matter when once it had got into the sewers, and anything done in that line was a deception. He should like the treatment of the sewage to commence earlier than was usually the case—namely, in the sewers themselves.

The Conference of Medical Officers of Health was continued during the day, under the presidency of Dr. Tatham, of Salford. A resolution was passed urging upon the Council of the Institute the desirability of rendering the Conference a permanent feature of the annual congress of the Institute.

Papers were read by Dr. John F. J. Sykes on "The

Digitized by Google

uniformity be desired, a panel on the opposite side may be furnished and fitted for a coal-scuttle. The plan adopted by Messrs. Young and Moss seems to us feasible and practicable. When, however, a "ventilator" is ordered, it must always be borne in mind that an "outlet" is only half that is necessary. If inventors wish their apparatus to succeed, they must insist on properly placed inlets also. If this be not done, in proportion as the outlet is efficient so will the cold air come whistling under doors and through cracks and keyholes, and the use of one or other device for the "exclusion of draught" will be the inevitable result.

DR BELL ON ADULTERATION IN 1886.

LAST year only forty-five cases of disputed analysis were referred to Somerset House. In twenty-four of these cases the reports of the public analyst were confirmed, while in the remaining twenty-one they were condemned as inaccurate. The result must be regarded as satisfactory. Even under the loose system at present prevalent, an enormous number of samples are analysed every year; the work is miserably ill-paid, and some of the analysts are not properly trained chemists. Considering that an appeal can be obtained in every case, it is significant that so few vendors should have ventured to ask for it. Some of the convicted traders are perhaps too poor to risk the expense, but there can be no doubt that in the great majority of cases the verdicts are correct, and the punishments not only not excessive but very inadequate. We do not doubt the substantial accuracy of the Somerset House analyses. Dr. Bell and his colleague are skilful and impartial chemists, and as every case submitted to them is the subject of dispute they no doubt use all possible care. Public analysts object chiefly to the revision of milk analyses, urging with some reason that the analysis of a stale sample cannot be as trustworthy as that of the same sample while fresh. The Somerset House chemists make a correction for the change produced by putrefaction, and properly give the benefit of any real doubt to the accused party, but it cannot be said that the method is perfectly satisfactory. The difference is commonly very small, and we do not see how the difficulty can be avoided without limiting the power of appeal, which would be unfair to the vendor. What is really wanted is a new Act, in which offences shall be more accurately specified, and a more stringent method of repression used.

SMALL-POX AT SHEFFIELD.

THE Sheffield Corporation have, in view of the extension of small-pox, and apparently so as to secure additional beds for acute cases in their infectious hospital, taken a convalescent home at Totley Gardens, and as the result a writ is about to be issued to restrain them in their proceedings. Difficulties will more and more arise as to the isolation of small-pox in our large towns and cities, and it may come to pass that the people who wish to protect themselves against that infection will, after all, have to fall back upon vaccination. But Sheffield is a borough which adjoins a wide expanse of open country, and a small-pox hospital could probably be placed where it would be at some distance from any such centre as that in which the other fevers have been successfully treated.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific medical men are announced:—Dr. Caspary, director of the Botanic Garden and Professor of Botany at Königsberg; Dr. Jacques Lachaise, Professor of Anatomy and Physiology in the Poitiers Medical School.

DERMATOSES FROM EMOTION.

THAT dermatoses may apparently be excited by neuroses is well known, but the fact that mere emotional excitement may develop skin lesions is not admitted in many quarters. Leloir, in writing on this subject in the *Journal de Méd. et de Chir. de Bruxelles* of July 20th, gives the following characteristics of the emotional dermatoses: rapid onset after the moral shock, and, should the dermatosis not immediately succeed the shock, a series of nervous troubles, such as pruritus and neuralgia, precedes the cutaneous eruption; the progress is rapid, and the lesion soon attains its maximum development; the dermatosis is always superficial, scarcely ever involving the deeper part of the skin, and being chiefly of the vaso-motor, catarrhal, or pigmentary sort. Excessive pruritus is a feature of these dermatoses; their duration is relatively short, and they are especially to be observed in females.

VACCINATION AND SMALL-POX IN LEICESTER.

DR. CORY, in a letter to *The Times*, reproduces a large part of our annotation last week on the above subject, and of our Special Commissioner's report last year, showing the importance attached by the sanitary authorities in Leicester to vaccination and revaccination, all allusion to which was omitted in the account lately given by Mr. Biggs of the immunity of Leicester. Dr. Cory ends by prophesying that the Leicester method of employing vaccination will infallibly break down "when small-pox equipped in epidemic array visits Leicester." He is doubtless right, but the point of our Commissioner's contention is that the control of slight importations of the disease is due to the use of vaccination.

UNIVERSITY COLLEGE FACULTY OF MEDICINE.

THE annual dinner which is to take place on Monday next at the Freemasons' Tavern, under the presidency of Sir Henry Thompson, will, we are told, fully equal the preceding dinners in its character of a pleasant *réunion* of old friends. Many tickets have already been distributed to men of all periods by the honorary secretaries, Mr. Pollard, Dr. Poore, and Mr. Stonham.

FIRES IN THEATRES.

AT a meeting of City Justices, held at Liverpool on Sept. 28th, it was resolved that a Committee of Justices be appointed to inspect the theatres in the city, and report to the bench before the licences are renewed for next year, and that they be empowered to call in professional aid if deemed necessary.

DR. DAVID M'KEOWN of Manchester, writing to a contemporary with reference to the railway accident which recently occurred near Doncaster, expresses the opinion that no investigation which fails to elicit answers to the following questions can be satisfactory or complete:—(1) What is the state of vision (both as regards acuteness and colour perception) of the persons in charge of the colliding train? (2) What was it when these persons were last tested, and when were such examinations made? (3) What is the practice of the Manchester, Sheffield, and Lincolnshire Railway Company in regard to periodical testing? By whom is this work done? and what is the minimum of the company's requirements in regard to acuteness of vision and colour perception?

DR. BRUCE has been appointed by a committee of the Metropolitan Asylums Board Medical Superintendent of the Northern Hospital, which has been opened by the Board for the reception of patients suffering from scarlet fever.

Digitized by Google

ance of excitement were to be advised, with bromides, and even occasional small doses of opium. The existence of a heart bruit at the apex or base in most cases was averred by Dr. Ernest Goodman and others, but was not thought essential by Dr. James Collins. Dr. Wood saw little good in looking to anything but the high temperature and its remedies—cold water and the hypodermic action of antifebrin. Dr. Stern objected to a temperature of 111° being considered as necessarily fatal. Dr. Austin Flint had had recovery after 111°, and Dr. J. M. Costa said that several of his cases reached 110°; they recovered by kneading with ice and irrigation of the body with iced water. Dr. Lloyd, of Her Majesty's navy, increased our vivid horrors of the Red Sea by saying that 90 per cent. of the deaths in the navy occur in that sea and in men addicted to liquor. Altogether, the result of the discussion is to raise our hope of antipyrexial measures in such cases, and to impress us with the importance of attention to good selection of drugs and instruments for hypodermic use.

MR. NETTLESHIP ON THE OPHTHALMIA OF PARISH SCHOOLS.

MR. NETTLESHIP'S report on the ophthalmia of Norwood Schools, the disease having been very prevalent, is a valuable document for all guardians responsible for such schools to consider. All medical men will agree that such schools have a power of generating chronic granular ophthalmic disease, which is the most serious factor in such outbreaks of acute ophthalmia as that which has led the guardians to seek Mr. Nettleship's advice. He shows the power of the schools to produce this disease in a striking way. Of 111 cases of decided granular lids, only 6 are new comers; the other 105 have been in the schools for more than a year. General approval, on the whole, is expressed of the arrangements of the school. But it may be assumed that the very existence of chronic ophthalmia in 66 per cent. of the children of a school shows something defective in hygienic conditions. Mr. Nettleship considers that the exciting causes of the recent outbreak were attacks of whooping-cough and measles, which occurred in the spring of 1886. But to these exciting causes must be added certain contributory causes, particularly the permanent presence of a large number of cases with chronic disease of the eyelids, rendering them peculiarly liable to serious mischief when exposed to the causes of acute ophthalmia. Another chief evil in such schools is the insufficiency of arrangements for isolation. His recommendations are—(1) the imposition of longer isolation; (2) more personal medical supervision for the detection of chronic disease not felt by the patient or noticed by ordinary attendants; and (3) the persevering skilful local treatment of each case The disease is an opprobrium of parish schools, and yet there can be little doubt that if Mr. Nettleship's views are carried out in letter and spirit, it might ere long be exterminated.

SCARLET FEVER IN FULHAM.

ACCORDING to a special report by Mr. Francis Egan, seventy-six cases of scarlet fever came under notice in the northern district of the parish of Fulham in the first half of this year, and owing to complaints as to milk infection attention was paid to this subject. In the end two cases of scarlatina were discovered at one of the country farms supplying a suspected dairy, but they were not antecedent to attacks in Fulham amongst consumers of the milk in question. The report concludes that the Fulham epidemic was only part of the metropolitan one generally. It is stated that the disease has tended to spread more amongst the well-to-do than amongst the poor, and it is implied that this may be due to the greater readiness with which the poor accept isolation in hospital. Exhaustive inquiry into the causes of the origin of the outbreak was apparently not possible.

THE GOVERNMENT OF INDIA AND THE DRINK QUESTION.

THE grave charges of Archdeacon Farrar and others against the Government of India of favouring the use of intoxicants for the sake of increasing the revenue are warmly refuted by Mr. Cust, late Member of Her Majesty's Indian Civil Service, who held the highest revenue posts in the Punjaub and north-west provinces under Lord Lawrence, and who bases his letter (to *The Times*) on a despatch from the Government of India, on the system of licences for the distillation and sale of spirituous liquors in force in the various provinces of India, signed by Lord Dufferin, Sir F. S. Roberts, and five other members of the Supreme Council. It is maintained that the high taxation is meant to discourage the consumption of the baneful drinks, and that this has always been, and is now, the policy of the great and good statesmen who have ruled India.

THE VOMITING CENTRE.

PROFESSOR TUMAS, who has been making a series of researches on the subject of vomiting, which are published in several recent numbers of Professor Botkin's journal, the *Ejenedélnaya Klinichestcaya Gazeta*, finds that in dogs and cats section of the medulla at the level of the fourth ventricle does not prevent the induction of vomiting by hypodermic injections of apomorphia. By touching different parts of the medulla with a weak solution of apomorphia, so as to induce vomiting, he was able to localise with tolerable precision the situation and extent of the vomiting centre, which he says lies in a space about 5 mm. in length by 2 mm. in breadth, before and behind the calamus, and in the deeper layers of the medulla. He believes that the absence of vomiting which is observed in ruminants, rodents, and some other classes of animals, is due to the absence in them of a vomiting centre, or to the very rudimentary condition in which it exists. In a rabbit in which he tried in every way to induce vomiting, no signs of gastric movement of that nature could be detected.

DRINKING METHYLATED SPIRITS IN EDINBURGH.

THE Relieving Committee of St. Cuthbert's Parochial Board have under their consideration a statement that numbers of cases become chargeable to the parish from the effects of drinking methylated spirits. As the whole matter has been referred to the chairman's committee, we shall await its report. But there seems some reason to believe that methylated spirits are taken, mixed sometimes with ordinary whisky and sometimes with naphtha, and even a little oil of vitriol, and water. According to one witness this was the composition of shebeen whisky.

NEW METHOD OF VENTILATION.

A PLAN for ventilating a room, which is, we think, sound in principle, has been invented by Messrs. Young and Moss. The ordinary fireplace is used to create a draught. The outlet from the room is close to the ceiling; from this point a tube descends, making a bend at the floor level, and reaching the exit at the commencement of the chimney. Between the floor bend and the exit is a cylindrical air chamber, which is said to efficiently prevent any back current into the room. The apparatus can be fitted to any ordinary fireplace, and in the drawing furnished is shown in connexion with the well-known "country parson's" grate. The ventilator is concealed by an ornamental panel, and, if

M. Thiriar examined a large number of arms in the dead-house when he was in charge of the post-mortems, and found this anomaly present in 12 per cent. of the cases. However, he has always succeeded in arresting hæmorrhage in wounds of the palmar arches, even when the tissues were suppurating, by a modification of Sir J. Simpson's plan of acupressure. He uses needles curved to a semicircle, and, passing them under the artery, brings the edges of the wound together and occludes the vessel by the application of a twisted suture, which there is no need to draw very tightly. He summarises his advice thus:—1. Direct ligature. If impossible—2. Twisted suture and acupressure. If unsuccessful—3. Ligature of humeral in the middle, if the collateral circulation has not had time to develop; above the profunda if it has. 4. Employment of compression, direct or indirect, forced flexion, forcipressure, styptics, &c., only as temporary expedients.

CANON JELF ON THE PREVENTION OF CONTAGIOUS DISEASE.

CANON JELF has recently been endeavouring to get some provision made for the cases of contagious diseases, which have increased to an appalling extent in Chatham and Rochester since the suspension of the C. D. Acts. He first wrote to the guardians suggesting that they should build a hospital for the accommodation of such cases, but they told him that they had no power to do so, their duty being merely to relieve cases of destitution. He has since arranged to write to the Home Secretary, laying the facts before him, and suggesting that it should be made a misdemeanour for a woman who has voluntarily entered a workhouse or infirmary with venereal disease to leave without a medical certificate that she is cured. The guardians expressed their readiness to support Canon Jelf in every way possible. The chairman remarked that they had already done what they could, not only by deputation, but by bringing to bear the influence of their members of Parliament, putting the case as strongly as possible, and pointing out that when a militia regiment was there sixteen women left the workhouse wards, but that no satisfactory reply had been received.

THE DRAWBACKS OF THE ANNUAL HOLIDAY.

THE "going away" and the "coming back" are full of risks to the annual holiday maker. He works steadily during the intervals between his vacations, and encounters special perils of *change* when he breaks off one mode of life to take to another. Wholly apart from the evils attendant on monotonous work and holiday-making respectively, there is the interruption of one rhythm and habit and the assumption of another. Those who have worked with their brains for ten months out of the twelve doubtless enjoy, and are, as a rule, benefited by, the substitution of muscle work for brain work for a spell of two months, but unless the change be well managed there are obvious risks consequent upon the suddenness of the call made on disused faculties. There is wisdom in a very gradual exercise of the muscular, the respiratory, and the cardiac apparatus in "recreations" when these particular parts of the organism have been long resting, and may possibly have fallen into a condition of imperfect nutrition. When, this being forgotten, ministers of State and members of Parliament, professional men, and 'brain-workers" generally, rush off to the moors and the mountains, it is not surprising that they occasionally find hearts, lungs, and limbs not strong enough for the new task suddenly thrust upon them. There is no mystery about the deaths, and "accidents," and "exhaustions," which are so common at the commencement of the annual vacation. The like is true of the resumption of ordinary work. Even though it be good policy and healthful to allow those parts of the organism which have laboured incessantly during ten months of the year to rest during two, it should not be forgotten that there is danger in too abruptly calling upon these resting faculties to recommence their ordinary activity. Those persons are wise who begin their holiday quietly and resume their avocations gradually. Better shorten the respite by a day or two, that the process of getting again into harness may be effected in a leisurely way, than rush home and back to work so hurriedly that half the good of the rest enjoyed is sacrificed by its too rude and tumultuous ending.

LORD ROSEBERY ON SHORTHAND WRITING.

THE Congress of Shorthand Writers, which is just over, and which commemorates at once the virtual tercentenary of the first known publication on this subject, the work of Dr. Timothy Bright, and the jubilee of the Pitman system, was opened by Lord Rosebery with an address as instructive as it was eloquent. After deprecating with pathetic humour as a responsible politician the merciless exactitude of Parliamentary reporters, he admitted and impressed the fact that the future of shorthand writing as an aid in the speedy transaction of business was far too little appreciated, and compared our own position in this respect with the more favourable condition of the American people. There certainly is no doubt as to the general truth of these observations, and the more widely we extend the meaning of the word business the greater practical force do they acquire. Besides the class of professional reporters, clerks and secretaries would, there is no doubt, find it profitable to master the details of the phonetic method. The possession of an art of so great utility might in these days of earnest competition—nay, probably would, other things being equal—decide the question of selection between rival candidates for an appointment. For rapid medical note-taking an acquaintance with shorthand would be equally valuable, and medical students might cultivate it with advantage. In their case, however, it must be presupposed that they will be content to preserve their notes of lectures in this abbreviated form, otherwise the work of transcribing would occupy too much of the limited time at their disposal. It is not necessary that we should discuss at greater length the many and manifest applications of this useful modification of written language, which must by this time have more than justified the best expectations of its originator as "an arte of shorte, swifte, and secrete writing by character."

SUNSTROKE AND THE WASHINGTON CONGRESS.

THE discussion on Sunstroke at the International Medical Congress was a good illustration of the general character of the work, and brought out many points of vital interest. The author of the paper (Dr. John Anderson) alluded to the part played by alcohol in the production of the disease, not only by its direct action on the brain but through the glands, and its influence in the heat-regulating function of the skin. He inveighed against the use of alcohol, and stated that the best drink for soldiers on the march was cold tea flavoured with lime juice. In grave cases his treatment is thus summarised: Strip the patient, recline the body, fan, douche, clean out the bowels with enemata, and give hypodermically the hydrobromate of quinine. He insisted on the necessity of the solution being clear, and the salt perfectly dissolved. He thought the quinine acted on the cardiac ganglia. Dr. Marston endorsed the views of the paper, and observed that irritation from the hypodermic injection could be obviated by the use of a pure solution and clean instruments. He made important remarks on the sequelæ of sunstroke—timidity, insomnia, dreams, excruciating headache, and even paroxysmal attacks of mania,—for which colder climates, sea voyages, and avoid-

claimed the same and paid all reasonable expenses incurred by reason of such detention." Under this Act hundreds of dogs are annually removed to the pinfold, detained there for three days, and, if not claimed sent to the Home for Lost Dogs. Here they are kept till they are sold or destroyed. Captain Nott Bower, the head constable, has issued a notice directing that dogs must be under control in the streets of the city—that is, held by a chain or string,—and that all stray dogs will be taken possession of by the police. The same dog which bit the two boys who died (one in the Royal Infirmary, the other at Wavertree) and the lady, Mrs. Atkinson, who has undergone the Pasteur treatment, also bit other persons, one of them being a lady under the care of Dr. Oldershaw, who has written to a daily paper protesting against the sensational and exaggerated reports in the papers, which are calculated to prejudice considerably any cases which present hopeful symptoms. Moreover, to keep these papers or the matters contained in them from the patients is next to impossible, and if it were, there are still plenty of "Job's comforters" willing to impart bad news. There are great differences in persons bitten by the same dog, differences of constitution, of degree of injury, and of promptitude of treatment, and it is to be hoped that no more fatal cases will occur.

CHOLERA INTELLIGENCE.

THE news of cholera in Sicily relates this week only to Messina and Palermo. In the former place the ravages of the disease are still very severe, no less than 881 cases and 387 cholera deaths having been recorded in the seven days ending September 26th. In Palermo the mortality, though still maintained, is by no means so great; here the deaths returned have amounted to 22, but the record is evidently somewhat incomplete. From the mainland of Italy cholera news comes only from Naples, where, according to the last return, 22 deaths occurred in four days; but a subsequent report, referring to the various places round the bay and in the province of Naples, is to the effect that within the last few days a marked improvement has set in. From Malta intelligence has also become intermittent, but it would appear that on an average some 5 deaths a day are still occurring there. From Naples as a centre cholera has now made its way over to the American continent, by means of a French vessel, the *Alesia*, which arrived at New York from Naples and Marseilles on September 23rd. There were then eight cases of cholera on board, but no reference to fatal attacks is made until the 25th, when two "additional" deaths were announced. On her arrival the *Alesia* was ordered into quarantine for a period of at least a week, and it is since then that the two deaths referred to, as also the spread of the disease to another steerage passenger, have taken place. No details of the methods adopted as to quarantine at New York are as yet to hand, except in so far as fumigation of the vessel was concerned, a process which we assume involved the landing of the passengers and crew.

CATCHING TRAINS.

THE Turks, who have a saying "Hurry is the devil," are not far wrong, particularly when the haste is to catch a train. All violent or strenuous effort is bad. When the organism has once attained its full measure of development, it seldom feeds—physiologically—beyond the requirements of its daily average life and work, and it is henceforth good chiefly as a "going concern." The margin of reserve strength at call for emergencies is seldom a large one, and those persons are ill advised who make a great demand too suddenly. It matters little what the demand may be, or on what part it is made. The policy of putting forth any great unaccustomed effort, whether of mind or body (to use a popular form of expression), after maturity, is unsound. Whether the fact that we generally begin to go down the hill of life soon after we reach its summit, instead of lingering on the higher plane, is accounted for by our habits of modern conventional life, may be doubtful, but the fact admits of no question. Practically the total length of life depends principally on the management of the middle age. The secret of longevity is, probably, skill in so economising the reserve of vital energy as to make it last out an unusual period. Most of the aged folk we know have lived pretty equably—which is a different thing from tranquilly—after the attainment of years of maturity. They may have worried and worked hard before, but they steadily maintained the habit—whatever that might be—which was formed at the turning point of middle age, between the ages forty and sixty. This done, the prolongation of life was chiefly due to an avoidance of special *efforts*. Occasionally the whole life consists in a series of efforts, and yet it lasts long; but then the "organised habit" of nutrition has been that necessary for a wide range of special calls on the reserves. If a man has been catching trains all his life in youth and from adolescence, he may continue to do so with impunity; but to begin this feat in mature age is suicidal, because the margin of strength held in reserve does not justify the special demand or respond to the call.

THIRIAR ON WOUNDS OF THE PALMAR ARCHES.

DR. THIRIAR, taking as his text the case of a man who had been unsuccessfully treated both by a pharmacist and a surgeon for a wound in the hand, which when he was brought into hospital was both bleeding and suppurating, gave recently an instructive clinical lecture to the Brussels students on the management of wounds of the palmar arches. He pointed out that there is, from a clinical point of view, a distinction to be drawn between these and other wounds of the palm which implicate only the collateral branches, a distinction which is not clearly stated in surgical works which students read. The latter class of wounds present no difficulty, and the hæmorrhage from them can be easily arrested. Not so, however, with the wounds of the palmar arches. Here, of course, the obvious indication is to search for the two ends and tie them. In consequence, however, of the tendency of the artery to retract, it is frequently impossible to find these ends without an amount of dissection which is undesirable. Perchloride of iron and other styptics hardly ever succeed, and they are to be avoided on account of the effect they produce on the surrounding tissues. The actual cautery is somewhat better if not too highly heated, but even this very frequently fails. Even if success results, it is usually only temporary, for the muscular coat of the artery is apt, as Dolbeau pointed out, to relax after a time, and permit hæmorrhage to break out afresh, in spite of any clots which may have formed. Similarly direct compression is seldom permanently successful. Compression of the ulnar and radial, forced flexion, and forced extension may be used as temporary expedients, for example, on the field of battle. Vanzetti's method of keeping the lips of the wound widely apart by means of hooks and that of forcipressure is not satisfactory, and Dr. Thiriar recommends that no time should be lost in trying cones of charpie and starch, elastic balls or sponges. The safest and best plan is to ligature in the wound if possible; if not, above it. In recent cases it can usually be done in the wound. Where it is necessary to tie higher up, it is of no use to tie the ulnar and radial; and if the wound is not very recent, and there has been time for a considerable amount of collateral circulation to have developed, even the brachial must be tied above the profunda. It is necessary to remember that the axillary artery sometimes gives off two brachial branches as high as the axilla itself.

Digitized by Google

right leg, producing a burn of the second degree. It had then passed down to the foot where the burn was of the first degree, and the strip of skin affected much narrower than above. The hat, coat, and trowsers were injured—as if torn—all along the course of the current, but they were not burnt in any part. The patient was treated with sedatives and some clysters, and in sixteen days was perfectly well. Dr. Hidalgo supposes that the pneumogastric was affected by the shock, which paralysed the respiration, and subsequently the heart's action, similarly to the behaviour of an overdose of chloroform. The indication, therefore, was to re-establish the respiration, and this was admirably fulfilled by the cold affusion, which fortunately was administered quickly, before the paralysis of the heart had become absolute.

ISOLATION OF FEVERS IN NORTH BIERLEY.

UNDER the arrangements by which the Bradford Fever Hospital has been transferred to the Bradford Corporation, a sum of £4000 has been handed over to the authorities in the North Bierley Union for the purpose of providing means of isolation for the several infectious fevers, and a preliminary meeting has been held to decide whether one central hospital or several minor institutions would best meet the requirements of the several districts. One single hospital has in many instances very distinct advantages over multiple ones, involving as it does one instead of numerous sites, administrative buildings, and other requirements. But, for success, the districts uniting in the erection of a single hospital should be so placed that the building can be easily reached from every portion of the area they include, and anything like undue aggregation of the sick should be avoided. In this instance we read of places having together over 120,000 inhabitants, and since these are scattered over a considerable area, we certainly incline to the notion which was brought before the meeting in the form of an amendment, that at least four separate hospitals, and not one only, should be provided. The worst of this, the more appropriate arrangement, is that each of these four hospitals would have to serve combinations varying from 20,000 to 35,000 a-piece, and it is certain that £1000 would not suffice for the needs of each of the districts referred to. Probably the most equitable arrangement would be for the sanitary districts included in the union to apply to be formed, under a Provisional Order, into a united hospital district; and then the hospital authority which was elected could utilise the money which has been handed to them in providing hospital accommodation at a point where it is most needed, borrowing money on the security of the rates of the combined area for the erection of other hospitals in the more outlying places as the need for them becomes apparent.

A SUGGESTION FOR MARKET GARDENERS.

THE dietetic value of fruit and vegetables is now as firmly established in rational theory as it has been from time immemorial recognised by the habit of mankind. Experience has taught both civilised and savage races that without the palatable and wholesome addition of vegetable food in due proportion, blood is no longer a purely vitalising and nourishing fluid, but a source of diseases traceable to faulty nutrition. Fortunately, there is hardly any part of the habitable earth where such food in some form is not obtainable, and certainly, whatever lack there may be in some quarters, there is none apparent in the markets of the metropolis. This remark, however, necessarily does not apply to every season, nor does it indicate that the produce of the native shires is fully represented on the stalls of dealers. In winter a dearth of fresh vegetables and of fruit is inevitable, while in the face of cheap and abundant importations from abroad, and of the relatively heavy dues charged by railway companies in this country, local farmers have not those facilities which are desirable in sending to the central market. We therefore observe with satisfaction that a beginning of better things has been inaugurated by some enterprising producers in Kent, and that for some time past vegetables, fruits, and preserves, cheap and of good quality, have come regularly to London by river from that county. The experiment having so far proved a success, we are informed that pickles, jams, and preserved green vegetables in large quantities may be expected to follow from the same source, and that even in winter such fare as cabbage and green peas will not be unknown on the dining-table. The example thus set by one county will not, we trust, fail to awake in others that spirit of imitation which will be its own best omen of success.

HYDROPHOBIA IN LIVERPOOL.

THE fact that three deaths from hydrophobia have occurred within a week in and near Liverpool is sufficient to demand more than passing notice. Two of these were alluded to in the letter of our Liverpool correspondent in last week's LANCET, and the third formed the subject of an inquest held by Mr. Husband, deputy coroner for South-West Lancashire, on the 26th ult., who observed that he had within the past few weeks held inquests on hydrophobia cases at Leigh Lowton Junction, and Wavertree, in addition to the present one. From the evidence adduced it appears that the deceased was a gardener, aged twenty-nine, and of remarkably fine physique. On the 25th ult. the employer of the deceased returned from the Continent, and got a scratch on the hand from the dog which bit the deceased, in consequence of which he told the deceased to be very careful and not go near it. On the following day the deceased went to him and showed him a wound on his arm. He had put his hands to the bars of the kennel and patted the dog; the latter seemed so friendly that he allowed it to go free, and then the dog bit him on the right arm. He was not at all a nervous man—rather the reverse. He went to Dr. Gorst of Huyton, who cauterised the wound, but recently all the usual symptoms of hydrophobia appeared, and the deceased died in great agony on the 23rd ult. It is noteworthy that both at this inquest and the previous one at Wavertree the deputy coroner dispensed with medical evidence, lay witnesses only being examined. Considering the fearful nature of this disease, and the efforts which are being made by scientific and other workers to discover its cure or its prophylactic, it does appear most important that in every well-marked case there should not only be medical evidence but a careful post-mortem examination, the spinal cord being the subject of special microscopic and other inquiry. It is also important that the dog should not be destroyed unless this is absolutely necessary, but should be removed to a place of safety and kept under the careful observation of a skilled veterinary surgeon. In this case the dog, a valuable stag hound, stated to be worth £50, was destroyed. The deputy coroner urged the importance of all dogs being kept under proper control for the next three months, observing that it was perfectly useless to issue orders in one district, while in another the dogs were allowed to wander about loose. If there were combined action the disease might be stamped out. It is satisfactory to observe that no fewer than fifty-four persons were summoned before the county magistrates for allowing their dogs to be at large within the townships of West Derby, Toxteth Park, and Garston; fines and costs amounting in the aggregate to £33 15s. were imposed. In the city of Liverpool the following general Act is always in force: "The police may take possession of any dog found in any street and not under the control of any person, and may detain such dog until the owner has

Digitized by Google

instances has experience verified the truth of these remarks experience not only of success but of failure. How many nervous children have passed through an active and useful lifetime in virtue of that very necessity for exertion which at first seemed a cruel hardship, and how many others have missed their purpose through that indulgent leisure which wrapped them in themselves, it would indeed be difficult to say. We may safely assert that any considerable number of life histories would furnish not a few examples of either event It is, however, a happy as well as an instructive fact that the morally tonic system in the management of such cases is taking the place of a more sympathetic and expectant method. We do not say this in order to advocate the application of any harsh and sudden hardening process to a timid nature, or the exclusion of judicious gentleness in training, but merely to advise the employment in education, where tone is feeble, of tonic measures. If there is in any family a history of nervous disease in certain members, and a probability that the morbid type has been perpetuated and is expressed in a wayward or passionate temper, in timidity, in languor, or any other of the protean features of the neurotic constitution, it does not follow that whims must be yielded to, exercise discouraged, and school-work forbidden. It is rather by the exercise of a wise firmness free from irritation, of moderate discipline, mental as well bodily, and, not least, by association with other healthier minds, that the atonic or loosely coupled faculties must be strengthened and taught to work with regularity.

THE PRACTICE OF MEDICINE AND SURGERY IN NEW SOUTH WALES.

It is natural, not to say essential, for every civilised community to consider the recognition which it will give to the profession of medicine. The nations which most pride themselves on their freedom are not able to ignore this question, neither are our colonies. They may at first give themselves little trouble about it. But it soon transpires that society and the individuals composing it have an immense interest in the creation of a body of men specially educated to deal with disease, and in the punishment of all fraudulent representations of the possession of such education. The Legislative Council of New South Wales in March last appointed a select committee to inquire into the state and operation of the laws for the regulation of the practice of medicine and surgery in that colony. They have not yet completed their work, but they have issued an interim report showing much need for legislation to prevent the public being misled by quacks and pretenders of all sorts, who with bogus degrees and false or fantastic titles deceive the unwary. One unqualified medical practitioner was examined, and threw a vivid light on the way in which some so-called diplomas are obtained. He possessed a diploma from the Edinburgh (!) University, Chicago, U.S. He did not attend to be examined. But he wrote a treatise on Venereal Disease and sent it on "along with the fees." After an examination through the post he obtained the diploma of Doctor of Medicine! He had appealed to have this diploma registered, but mercifully had been refused. He has been (as might have been anticipated) convicted of distributing obscene literature. Another witness stated that there are 1000 registered practitioners in New South Wales, and that 100 are registered annually in Sydney. This gives a proportion of practitioners to population about twice as large as that in Great Britain. A homœopathic physician stated that he had no diploma beyond being registered in the London Homœopathic Directory—certainly a very infinitesimal qualification. But this gentleman's claims were respectable compared with those of others. The herbalists are a very numerous host. One, in particular, did all his diagnosis in a state of clairvoyance, getting 10s. before the commencement of the process. The evidence of Mr. Andrew Honison, M.B., secretary for ten years to the Medical Board of New South Wales, disclosed the risks of a state of the law highly favourable to audacious scoundrels of all sorts, with forged or bogus diplomas, making it difficult to refuse them registration and impossible to remove them when once registered. If some legislation is not attempted after this inquiry, we pity the inhabitants of Sydney, especially the poorer sort, who are evidently surrounded by men who play on their ignorance and their fears. Mockery in any matter is hard to bear, but in the hours of disease and danger to have a forger or a knave come to one in the garb of a State recognised and registered doctor is a public evil of the worst kind. One of the witnesses stated that only a statutory declaration of identity was required from persons holding foreign qualifications, and that a person once placed on the register by the Medical Board could not be removed. One witness stated that he had been employed by a firm who traded as a Remedy Company, and extorted money by playing on the fears of patients. Any person may practise and may call himself anything he pleases. An unqualified person may be called as a medical witness by a coroner. One witness mentioned that a coroner was an unqualified practitioner, and sat in judgment on one of his own fatal cases! We cannot doubt that a committee which has exposed such a loose and dangerous state of the law will not consider its work done until it has urgently recommended legislation for requiring more strict evidence of regular medical education and examination, and making penal the use of titles and designations which defraud the public and grossly injure respectable medical men.

COLD AFFUSION IN APPARENT DEATH FROM LIGHTNING.

Dr. Hidalgo of Mexico brought before the Academy of Medicine of that city, at a recent meeting, the case of a man who was struck by lightning, and was at first thought to be dead, but who, after having had, at the suggestion of a passer-by, a large quantity of cold water thrown over him, began to show signs of vitality. He did not at first receive any medical treatment, so that the early history of the case had to be obtained from the relatives. After being brought home, water was still poured over him until he spoke for the first time, saying he was cold, and begging that this treatment might be stopped. He was then put to bed. During the night he did not sleep, but kept talking in a delirious manner, and complaining of pain, especially in the head. When asked what was the matter, he said at one time that he had something the matter with his chest, and at another that he had rheumatism all over, but he made no reference to the lightning. Dr. Hidalgo saw him the next day and found him in a semi-comatose state. The pulse was 75, full and compressible, the temperature normal, the respiration rather rapid. He was so deaf that he could only be made to open his eyes by shouting close to his ear. The pupils were contracted. He complained of pain all over, but especially in the head and arms. He had passed three badly smelling liquid stools during the night. He was neither hungry nor thirsty. The electric spark had entered the upper part of the right parietal region just behind the auricle. The scalp was burned over a surface of about 4 by 5 centimetres, and a spot of dried blood was seen on the upper part of the auricle. The right side of the neck was reddened as by a burn of the first degree; below this, as far as the umbilicus, the effects were equal to those of a burn of the second degree, of the width of about 15 centimetres at most, but very irregular in its dimensions. The electric fluid had passed down the inner aspect of the

Digitized by Google

but there is no evidence of its propagation by water or other ingesta. The period of incubation is remarkably short, never exceeding twenty-four hours. M. Brouardel, in order to check the spread of the epidemic, organised, with the assistance of the house-surgeons of some of the Parisian hospitals, a special medical service for disinfecting the clothes and cottages in the affected areas; and the chief feature of this organisation was the formation of a relief convoy, comprising a hand engine and apparatus for steaming the clothes, bedding, and other furniture. The epidemic has now practically subsided.

THE DURATION OF SCARLET FEVER INFECTION.

COMMENTS have more than once been made as to the length of time during which scarlet fever patients are retained in the hospitals of the Metropolitan Asylums Board, but they have mostly emanated from persons ignorant of the disease. Every medical practitioner knows the danger of the desquamating stage; but it may be a question whether the danger which attaches to a patient necessarily lasts as long as the process of desquamation does. An ordinary patient has finished desquamating and is regarded as free from infection in about six weeks from the date of the eruption, but there are occasions when longer isolation is needed, and it has often been held that even the firm skin from the heels and soles of the feet must have become thoroughly detached before a patient can leave the hospital with safety to others. These are the cases that mostly call for unusually long detentions, and Mr. Corner, medical officer of health for Poplar, apparently has such a case in view when he publicly calls attention to the fact that a patient sent in to one of the metropolitan hospitals by him was detained over nine weeks. He at the same time calls attention to the common belief that infection continues so long as the outer skin has not wholly desquamated, a matter which he regards as an open question. Proof one way or the other is at present difficult, and so long as this is the case the authorities of fever hospitals are right in taking the safer course of the two. We may, indeed, be certain that, with the grave pressure for beds which the Asylums Board are now experiencing, they are not likely to detain patients longer than their medical advisers deem to be really necessary in the interests of both the public and the patients.

THE CRIMEA AS A HEALTH RESORT.

DR. F. WEBER, in an article published in the *St. Petersburger Medicinische Wochenschrift* gives an account of the different seasons in the health resorts on the southern shore of the Crimea. The climate of this region presents many attractions. There is a particularly large number of fine days, a long summer and a mild winter. It is, however, subject to numerous winds, which make it necessary that invalids should choose a dwelling which is well built, so that they may be protected from the inclemency of the weather on the days when they cannot get out. The portion of the Crimea which Dr. Weber writes of is a strip of land two or three miles in breadth, lying between the southern shore and the Jaila Mountains, which are some 5000 feet high. He divides the year into four cure seasons: the spring, or kefir; the summer, or koumiss; the autumn, or grape; and the winter. In April and May koumiss is not so good as it becomes later on, when the cattle are able to get better fodder; kefir and milk can, however, be had to perfection, and hydropathic and mineral water treatment can be carried on. Kefir and koumiss have been manufactured on scientific principles by medical men, but these gentlemen have never been able to make them so well as the Tartars and Greeks who trade in them. The summer is of course the chief season for baths of all kinds. Jalta itself is too hot to be agreeable, and even its regular inhabitants seek higher and cooler ground. This is the great time for koumiss; autumn is the chief season in the Crimea, especially for Jalta, which is generally filled to overflowing. The grapes are said to be particularly suitable for the grape cure. Until within the last few years everyone left Jalta and the rest of the south of the Crimea in the winter, but lately arrangements have been made for taking advantage of the superiority of the winter climate over that of most parts of Russia by constructing hotels and *pensions* suitable for winter visitors. Since the catastrophe in the Riviera a good many people have felt disinclined to go there, and although Jalta can hardly claim to equal Nice as a winter health resort, it is found to afford a very fair substitute for it in the case of persons with pulmonary affections who cannot manage a very long journey. Up to Christmas (Jan. 6th) koumiss can be depended on. After that time, however, it is not to be recommended. Dr. Weber states that meat powder thickly spread on bread-and-butter is largely and successfully used as nourishment for patients after the koumiss has to be given up. He finds that patients with hectic lung troubles who come to the Crimea early in the season—say before the middle of October—derive much more benefit from their stay than those who arrive in January or February, as the former have time to become acclimatised before the severe weather sets in.

TOILERS TO THE LAST.

THERE is nothing more pathetic than the dogged resolution of unvanquished poverty fighting beneath a weight of years the unremitting battle of life. Full of meaning in this view are the following figures relating to the licensing work of the Metropolitan Police:—

Class.	No. licensed.	Over 60 years of age and under 70.	Over 70 years of age and under 80.	Over 80 years of age.
Hackney drivers ...	14,852	850	117	3
Stage drivers	4,853	112	13	1
Conductors	6,615	25	—	—

A community numbering in all more than 1100 individuals, every one stricken in years, and all actively engaged in attendance upon the public vehicles of the metropolis! It is an interesting and a notable fact that, in a body of 20,000 men, four octogenarians should be found capable in eye and hand of navigating the crowded thoroughfares of London; but it is more interesting and more notable still that the public should hear of this battalion of veterans, not in the dithyrambs of political or philanthropic oratory, but through the medium of a sympathetic reference to them in the annual report of the Chief Commissioner of Police.

THE PREVENTION OF NERVOUS DISEASE.

WE are indebted to Dr. Russell Reynolds for a simple but scientific exposition of the power of preventive medicine as applied to the treatment of nervous conditions which are liable to give rise to allied forms of actual disease. The drift of his observations at the Bolton Congress of the Sanitary Institute was as follows:—Prior occurrence does not establish heredity, but even where predisposition exists, disease characteristic of a constitutional type may arise *de novo* through mismanagement of the individual affected. It is also to be remembered that expected nervous diseases can often be prevented, if the system in which they arise, instead of being pampered into illness, is refreshed by good food and discipline, and so developed to the level of its normal health. In how many

Digitized by Google

some effect on calculi already formed, as well as on the "calculous diathesis." He remembers being struck with the appearance of a stone—he does not say of what kind—which he saw removed from a young man's bladder, and which, though hard in some parts, was so friable in others that it could be broken down with the fingers. On questioning the patient, it was found that he had for some time taken ceterach by the advice of an old native medicine man, and that while he was doing so he had remarked that he passed more urine, and that it contained gravel. The pain, however, did not diminish, and so he lost faith in the treatment and gave it up. It is to be remarked that the use of ceterach in urinary calculi is by no means new. Dr. Pereira does not explain what relationship he supposes to exist between the "calculous diathesis" which leads to urinary calculi and that which produces gall-stones, or why a remedy which is useful in one case should be prescribed in the other; still his facts, such as they are, are worth noting, and they seem to have interested the members of the Mexican Academy of Medicine, before whom they were brought, and who had the opportunity of examining the various gall-stones and gravelly matter passed with the fæces, as well as the partly friable vesical calculus, upon which Dr. Pereira's suggestions were in part based.

THE REPORT OF THE HOWARD ASSOCIATION.

THE Howard Association have just issued their annual report on the present state of prisons and reformatories and the means best adapted for the prevention and punishment of crime. Some of the observations on the boarding-out system as employed for the arrest of juvenile pauperism and crime are well worthy of consideration. The committee of the Association claim for this system a marked advantage over that of the reformatory and industrial school, inasmuch as it secures, as far as possible, the separation of children of this class from their earlier and hurtful surroundings, their release from the frequent hardships of life in a public institution, removal of the doubtful benefit of mutual intercourse, isolation in case of illness, and a free allowance of fresh air and healthy exercise. The ultimate aim of this movement is the emigration of these children to a British colony, and the advantages detailed above are certainly conducive rather than otherwise to the successful attainment of that object. With reference to the prevalence of disease, we note that the report mentions ophthalmia as having been particularly common in one industrial school, and the treatment as directed rather by energy than skill. The cost per child of maintenance on the boarding-out system is considerably less than on any other. The preference accorded to it by the Association is thus on various grounds a rational one. On other matters connected with crime and prison management the report affords details of some importance. The close connexion between criminality and drunkenness is not for the first time exposed, and the influence of the temperance movement in lessening the number of punishable offences is acknowledged and strongly advocated. So-called "working men's institutes" are treated with equally vigorous reprobation, and are shown to be in many instances merely public-houses of an unusually degraded character. The salutary effect of the teaching of lady visitors in prisons is commented on. Their peculiar fitness to instruct and advise prisoners of their own sex, it is truly said, is such as no chaplain can pretend to. In referring to the murder penalty, a justifiable regret is expressed in the report that the action of law with regard to its infliction is far from regular, and cannot fail to excite an earnest desire for some clearer legal definition than is now available, of the nature of the crime for which it is the sole expiation.

THE EPIDEMIC OF MILIARY SWEAT RASH IN FRANCE.

IN many of the central departments of France an epidemic of a rather curious character has prevailed during the early part of the present year. Under the title of "L'Epidémie de Suette Miliare du Poitou," M. Brouardel has contributed to the Académie de Médecine the results of the elaborate investigations made by the Commission charged with the examination of the epidemic. It appears that on March 16th of the present year there appeared during an epidemic of measles a case of "suette miliare" in a young man aged eighteen, living at Sillarde, in the canton of Lussac-les-Châteaux; this case appears to have been the first link in a long chain of cases which were not confined to the district first affected, but appeared also in neighbouring departments. The symptoms of the disease were usually preceded by ill-defined prodromata, such as feverishness, weakness of the legs, and general malaise, followed the next night by copious sweating. The nervous symptoms were continued feelings of suffocation, sometimes increased into paroxysms, a sense of epigastric constriction, palpitations, agitation, and delirium. Cramps and contracture of muscles were also observed. The tongue was furred and the bowels constipated. In the first stage cough is habitual, and epistaxis generally abundant. The second period commences with the appearance of the eruption, which presents two chief features: first, a miliary papule, transformed later into a vesicle, which finally discharges; and, secondly, a polymorphous erythema, which may be arranged under three forms—a red rash, a measles-like eruption, and a purpura. The measles-like rash first appears, and is followed by the scarlatinal and purpuric characters. Sometimes the eruption remains rubeoliform, or it may commence as a scarlatinal rash. The face is the first to show the eruption, thence it spreads to the neck, trunk, upper limbs, and finally to the legs. The veil of the palate is often speckled with red. The forearm and dorsal surface of the hands are also seats of election for the papules. The legs are often less affected than the rest of the body. What is known as the "suette blanche" is composed of papules which remain hard and opaque. Frequently the eruption comes out in successive crops, which do not exceed two or three in number. This mode of evolution must not be mistaken for relapses of the malady. The eruption disappears completely and rapidly, but occasionally the purpuric spots remain a long time. During the eruptive period the fever is less intense, and the stomach derangement and the feeling of malaise are less pronounced. The constipation continues, and the stools have an offensive odour. The urine is scanty and sometimes suppressed. Very copious melæna has been noted. The evolution of the disease is completed by a desquamation of the skin, which occurs locally and in large flakes, especially about the fingers and palms of the hand. The desquamation supervenes soon after the appearance of the skin rash, and may even accompany the latter; it may begin on the face at the same time that the eruption is breaking out on the legs. The malady, in reality, terminates when the eruption commences to pale. Convalescence is characterised chiefly by its slowness, and this may be equally the case with slight as with severe degrees of the affection. The disease differs from measles in the circumstance that the rash appears on the second day after the premonitory symptoms set in, and also in the marked desquamation. Children are more liable to the disease than adults. The perspiration is profuse. The epidemic has been particularly severe this last year, for of 13,000 inhabitants in the district of Montmorellon 1700 were attacked, and the average mortality was 12 per cent., though in some villages it reached as much as 33 per cent. It is contagious,

Digitized by Google

reported is induced by exposure and what is commonly called "chill," it is a longer period than one would *a priori* be prepared to expect. Another striking feature of the report is the contrast which it exhibits between the causes of incapacity and the causes of death. Some differences—even some contrasts—one would anticipate, For instance, no one will feel any surprise that rheumatism, which is responsible for only one death out of seventy-four, should be a source of incapacity in 15 per cent. of the cases of invalided officers. But it is rather noteworthy that injuries, which come next to rheumatism as the causes of incapacity in twenty-nine cases, or 13 per cent. of the whole number, should not be chargeable with a single death if two cases, the one of accidental drowning and the other of suicide, be disregarded. It looks as if the British criminal had a wholesome dread of taking life, even when at his times of violence he is most dangerous to viscus and limb. It looks, moreover, as if he had a curious proficiency in the art of inflicting bodily damage on his fellow-creatures, whom he is cunning enough to disable, without killing them.

INFANT MORTALITY IN ENGLAND AND IN FRANCE.

THE Conseil Supérieur de Statistique in France has recently issued its bulletin for the session of 1886, from which it appears that the subject of infant mortality came under the discussion of a sub-committee during the year, and papers on the subject by M. Lafrabrègue and by M. Bertillon were submitted to the committee and discussed. The paper of M. Lafrabrègue contains a statement with regard to infant mortality in England, which is as remarkable for its inaccuracy as it is for the misconception it displays as to the system of registration in this country. M. Lafrabrègue's paper gives a table comparing the proportion of deaths under one year to living births in seventeen European States. This table is based, it should be said, upon the international figures for the years 1865–83, published in the Italian Report on Vital Statistics for 1884. The table shows that in these European States the deaths of infants under one to a thousand living births ranged in these years from 105 in Norway and 122 in Scotland, to 308 in Bavaria and 313 in Wurtemberg. The figures for England and France stand at 149 and 166 respectively. M. Lafrabrègue remarks: "According to these figures infantile mortality in England and in Scotland is lower than in France, *but this is not the case.*" Fortunately this statistician proceeds to explain his ground for making so dogmatic an assertion. It is explained, as is well known, that the law in France insists upon the "inscription" of all births within three days of their occurrence, and that all children who die previously to the inscription of their birth are recorded as still-born; in England, however, we are told that fifteen days are allowed for registration of deaths, and as no record is made of still-births, it follows that those children dying within fifteen days of birth are not recorded either in the birth or death register, hence the low rate of infant mortality shown by English statistics! Similar statements have before now been made by French statisticians impugning the accuracy of English statistics of infant mortality, but M. Lafrabrègue has exceeded his predecessors both in the breadth of his assertion and in the inaccuracy of his statement. Even if we admit that the English registration system is defective, both for the non-registration of still-births and for allowing so long an interval for the registration of births, the law enacts that information concerning deaths should be given within five (not fifteen) days; and the law is imperative, imposing penalties for non-compliance, that *all* births and deaths shall be registered, even if the infant should only once have breathed. The English law is at any rate free from the statistical defect of the French law, which records infants as still-born that may have lived three days. It is quite possible, and indeed probable, that a small number of births in England, in spite of the compulsory law, escape registration; but the effect of this would certainly be to overstate the rate of infant mortality, and may for the present purpose be disregarded. It is also possible that the deaths of a few infants may, in spite of heavy penalties for non-registration and also for representing a live-born child to be still-born, escape registration; but the following figures afford the most conclusive refutation to M. Lafrabrègue's assertion that the deaths of infants dying under the age of fifteen days are not registered in England. Of forty thousand deaths of children aged under one year, registered in England and Wales, in various urban and rural districts in 1874-78, more than 20 per cent. were of infants under the age of two weeks; 13 per cent. were of infants aged less than three days, and 8 per cent. of infants aged less than one day. It would therefore appear that, as no less than 13 per cent. of the registered deaths of infants under one year of age in England occur in the first three days of life, few of which would be recorded as deaths under the French system, there is more than a probability that the comparison of English and French official statistics understates the real excess of infant mortality in France, rather than considerably overstates it, as M. Lafrabrègue so confidently asserts.

TREATMENT OF GALL-STONES.

DR. SAMUEL MORALES PEREIRA, of Puebla, Mexico, gives an account in a Mexican medical journal of a case of "Biliary calculus diathesis" with enlargement of the gall-bladder, in which he found a decoction of a well-known fern, *Asplenium ceterach*, or *doradilla*, as it is called in Spanish, of great value. The patient was a gentleman of good general constitution, who had suffered for a long time from pain of a more or less periodical character in the hepatic region. His digestion and his temper were considerably affected. He had applied to a number of medical men, but had never derived any benefit from their treatment. On examination, the right hypochondrium was found to measure six centimetres more than the left, the region of the gall-bladder being distinctly enlarged and tender to the touch. The hepatic dulness in the axillary line was of normal breadth, but it extended five or six centimetres beyond the normal in a downward direction in the mammary line. On changing the patient's position no alteration in the situation of this abnormal dulness could be detected. The patient, on being asked, said that his urine deposited a red sediment, and that he had at times passed calculi with his stools. Dr. Pereira, having had experience of the good effects of ceterach in gravel and urinary calculus, and believing that it exerts an influence in "calculous diathesis," decided to employ it in this case. A decoction of half a drachm of the plant in five ounces of water was ordered four times a day. During the first twenty days no effect was observed. By the end of another twenty days the symptoms of mental irritability had disappeared, and the pain in the hepatic region had very greatly diminished. In fifteen days more the tumour in the region of the gall-bladder had become much less perceptible. The patient had been kept on milk and broth, which he did not at all like. He had passed three gall-stones and some gravelly matter with his stools there having been some severe hepatic pain. After this the patient continued to improve, though it was not easy to convince him that he was doing so. The amount of ceterach was diminished, and capsules of taurin prescribed, belladonna frictions being also applied to the hepatic region. He passed a succession of gall-stones, and the whole of the abnormal physical signs as well as the subjective symptoms passed away. Dr. Pereira hazards a suggestion that ceterach may have

It seems more than probable that the least trustworthy portions of the return relate to two points on which information was more especially desired, and which would have been undoubtedly valuable if trustworthy—namely, the extent to which the working classes are unemployed, and the nature and amount of assistance received when out of work. It would evidently be useless to base any conclusions on these branches of the subject upon the untested statements of the working men themselves, who, with visions of State aid in prospect, would naturally be tempted to strengthen their claim for assistance. Therefore, while Dr. OGLE'S report undoubtedly contains much interesting statistical material, it is difficult to say in what direction it contains information that can be made practically useful.

If we turn to Mr. BOOTH'S paper upon the condition of the population in the Tower Hamlets, which division includes the five unions of Whitechapel, St. George's-in-the-East, Stepney, Mile-end, and Poplar, we find that he has attempted, in accordance with a scale of his own, to divide the population into three classes, and calculates that 65 per cent. are above the line of poverty, 22 per cent. are on the line, and 13 per cent. are below the line, including the lowest classes, with the casual and very poor. Should Mr. BOOTH be able to extend his inquiry over other parts of London, applying the same system of classification, the value of his information will be much increased; but to be able to turn such information to practical account we need to go deeper, and further behind the scenes, than seems possible in any such inquiries as those instituted by the President of the Local Government Board or by Mr. BOOTH. There is comparatively little use in knowing, even accurately, the extent and amount of real and grinding poverty that exists among us, unless we can derive from that knowledge some means for controlling its amount and lessening the consequent suffering. Mr. BOOTH, speaking of his "lowest class," which fortunately constitutes only 1½ per cent. of the population of the Tower Hamlets, describes the life of these people as "mostly a savage life with occasional vicissitudes of extreme hardship and occasional excess." The "casual and very poor" is a larger class, making up his 13 per cent. who fall below the line of real poverty. What we really want to know is so much of the history of this class as will teach us the real cause of their distress. They doubtlessly consist in unknown proportions of those born in the class who have never had a chance of rising out of it, and of those who may be called the failures and the drift from all the classes above them. Society owes to the former some kind of reparation, but how are we to help the latter? If, however, we can find the way to ascertain more definitely the true causes of the poverty and degradation of the lowest classes, we shall, at any rate, be in a better position to attempt the removal of this blot upon our boasted civilisation.

WE are asked by Sir W. Guyer Hunter, M.P., to state that a recent announcement in an evening contemporary, to the effect that he would shortly receive a Government appointment abroad and would resign his seat in Parliament, is totally without foundation.

THE preparatory Medical School in Toulouse is to be advanced to the rank of a medical and pharmaceutical school *de plein exercice*.

Annotations.

"Ne quid nimis."

THE SCARLET FEVER EPIDEMIC AND THE ASYLUMS BOARD.

THE prevalence of scarlet fever in the metropolis still continues, and has undergone a further increase, as many as seventy-two fresh patients having been received into the Asylums Board hospitals in a single period of twenty-four hours. But by dint of considerable energy, two of the admirable pavilions at Winchmore Hill were ready for the reception of convalescents early this week, and this gave the managers more room for acute attacks in their other hospitals. Two more are now ready; efforts will be made to prepare more accommodation at Winchmore Hill, and by this means it is hoped that the emergency may be met. How far this will be the case yet remains to be seen, but unless an earlier abatement of the epidemic takes place than has been usual in former autumnal outbreaks, hospital accommodation in London will before long be put to a very severe strain. At the last meeting of the managers the various arrangements that had been made were announced, and a matter was then brought before the meeting that shows a real difficulty in the relations between the Local Government Board and the managers. Preparations have to be made to meet any future small-pox epidemic, and the managers desired to build hospital blocks on the plateau of their site at Darenth. This, it appears, the central authority have all along objected to, and they required that the buildings should be placed in the valley part of the estate. For eight or nine months matters have been so strained that everything has been at a standstill, and in the end the managers called in the services of Mr. Rogers Field, M. Inst. C.E., who has, on grounds which involve both medical and engineering points, altogether condemned the valley site. On the receipt of this report, but, as the letter said, "in deference to the wishes of the managers," the central authority now altogether give in, and Sir Edwin Galsworthy, with good reason, complained bitterly that the managers had thus had their preparations put off until winter was approaching. This incident makes it more than ever difficult to understand where the Asylums Board ought to turn for skilled counsel in their work; and it certainly is more than strange that the central body, with a staff of some eighteen engineer and medical inspectors, could not, until an outside adviser was called in by the managers, possess themselves of the information which they should have had before they opposed the managers, and which could easily have been obtained by them some nine months ago. Obviously there is a vacancy which someone is called upon to occupy, and this is probably the explanation of the statement in Dr. Dudfield's last report to the Kensington Vestry, to the effect that in the last small-pox emergency the Local Government Board and the Asylums Board followed the advice that he had given them. But whoever has the responsibility of being adviser to the Government should receive the emoluments properly attaching to the post.

HEALTH OF THE METROPOLITAN POLICE.

FROM the report of the Chief Surgeon upon the Metropolitan Police it appears that the cases of sickness occurring during the year 1886 in a force of 13,257 men have numbered 6974, giving a proportion of 52 per cent. The daily loss of efficiency to the force through sickness averages 3·7 per cent., so that apparently the average duration of sick leave in an individual case is about six-and-twenty days. This would seem to imply a considerable proportion of severe attacks, and seeing that a very large part of the sickness

affected part; but we may ask whether, had the staphylococcus not been inoculated, the bone-marrow or the cardiac valve would have become the seat of virulent inflammation. Of course the soil is one element, but the seed is quite as essential; and we imagine that although we speak of a specific disease being due to a germ, we imply that the body is apt to receive that germ. We must therefore confess to some disappointment in Professor SEMMOLA'S counsel that we should study the physical and chemical conditions of the blood and tissues, which would be a far harder task than the determination of specific bacteria. Nor can we see that the knowledge of the one factor is of any use without the knowledge of the other. We admit that there is a future before therapeutics in respect to modifications of the soil more hopeful than in actively germicidal methods; but why, then, decry the study of bacteriology and paint in such dark colours its baneful effect on pathology, when, after all, its teachings are furnishing the very motive for such profounder knowledge of the workings of the body which is so much desired? If Professor SEMMOLA intended to damp the ardour of bacteriologists he will have failed in his object, for we can see in his address nothing but an encouragement to them to further investigation.

ALIKE from the standpoint of politician, statist, or philanthropist, the condition of the working classes is a subject teeming with interest, and of vast importance to the nation's welfare. It is eminently satisfactory, therefore, to welcome any honest endeavour to throw light on this complex question. Whatever opinion may be held as to the value of a large proportion of the figures now set before the public as the result of the recent inquiry into the condition of the working-class population in certain typical districts of London, the recognition by the Government of the importance of the subject, implied by the inquiry, is a good sign of the times.

The object of this inquiry, carried out under the direction of the President of the Local Government Board, was primarily to test the actual condition of the working classes as to birth-place, civil condition, housing, employment, and means of subsistence when out of work. No material difference of opinion exists as to the value of such information if trustworthy, but few of those who read Dr. OGLE'S report to Mr. RITCHIE upon the results of the inquiry will be inclined to think that the inherent defects in the statistical material collected have been too firmly insisted upon.

When Mr. CHARLES BOOTH, a few months since, read before the Royal Statistical Society his elaborate paper on the Condition of the People in the Tower Hamlets, objection was, in some quarters, made to his figures because his information was in the main derived from the School Board visitors, who, it is more than probable, would often be systematically misinformed on many points bearing, even indirectly, upon the ability of the working classes to pay school fees. These objections to Mr. BOOTH'S information, however, apply with even increased force to the figures in the report now officially published, which were supplied by the working men themselves. Mr. RITCHIE'S inquiry was undertaken at the end of March last, and the idea of submitting the long list of questions to the working men was, at any rate, not a happy one. The men, not unnaturally hoping that the information might be made the basis of State aid, could scarcely be expected to resist the temptation of understating their resources and overstating their misfortunes. Dr. OGLE points out, however, that apparent incongruity in the figures must not too hastily be attributed to wilful misstatement. If you ask a skilled artisan who is temporarily engaged as an unskilled labourer whether he is out of work, it need cause little surprise if he answers in the affirmative, although the tabulation of such information must necessarily be misleading. Similar contradictions are involved in the return of 214 men actually in work, and yet tabulated as permanently disabled; this probably signifies that the workman is physically unequal to follow his ordinary occupation, although he is able to perform some other and probably lighter form of labour. While admitting, however, the probability of "considerable misstatement" on many of the points concerning which information was sought, the tabulated results obtained for the several occupational groups are not without value for comparative purposes, since there is no reason to believe that the tendency to inaccuracy was greater in one occupation than another.

The inquiry embraced nearly 30,000 working men living in St. George's-in-the-East, and in parts of Hackney, Deptford, and Battersea. If account be taken of the wives children, and other relatives residing with these working men, the population dealt with exceeds 125,000. Perhaps the most striking fact brought out by the return is the small proportion of the foreign element among the working men dealt with. The mean proportion of workmen born abroad is only 5 per cent., and in only six of the occupational groups does the proportion exceed 9 per cent.; these groups are sugar bakers, tailors, cigar and tobacco workers, furriers (with skin dressers, &c.), bakers, and bootmakers. If these occupations be excluded, the proportion of foreigners falls to 2 per cent. These returns, it is fairly said, "scarcely support the current belief that foreign labour is largely supplanting native labour in London." Neither do they support the general impression that at times of depression the condition of the London labourer is affected by the large amount of provincial immigration. No less than 97 per cent of the working men stated that they had lived in London more than a year, and even of the foreigners 94 per cent. had lived over a year in London.

If we can trust the figures bearing upon the housing of these working men and their families, it is satisfactory to find that 59 per cent. were returned as living in three rooms or more, 21 per cent. in two rooms, and only 17 per cent. in single rooms. It is to be feared, however, that these figures are somewhat invalidated by the lodger complication, which by the form of the return could not be fully taken into account. A similar disturbing element affects the return of weekly rent; but it may be stated that the average weekly rent returned by the whole of the working men was 6*s.* 2*d*, while the average weekly earnings was 24*s.* 7*d.*; thus the proportion of earnings spent in rent was 25 per cent. The variations in rent, earnings, and room accommodation in the various occupational groups is not without interest, and, as suggested by Dr. OGLE, their relative proportions are more trustworthy than the figures for any individual group.

the public and the profession have been abundantly provided with doubting criticisms as to whether there is, after all, any true relation between bovine disease and scarlatina in the human subject, and the result has been a demand for further scientific investigation by the Government departments dealing with the prevention of human and animal diseases. Lord BASING would amend the sanitary laws, because there is "no finality in legislation." The proceedings of the Sanitary Institute have well shown that we are yet a long way off the time when finality will be reached as regards the saving of life from preventable diseases, and it would be a national disgrace if, for mere financial reasons, any check were placed upon the development of scientific research in this direction. By all means get rid of centralisation as regards mere administrative interference by the Local Government Board in matters that have primarily a local concern, and that can properly be dealt with by local medical and other advisers; but there is no such demand on the part either of the public or of the profession, as Lord BASING'S presidential address would imply, for any restriction as to researches by the central authority on matters affecting public health in its widest sense.

No better illustration of the scope there is in medicine for divergent opinions could be afforded than the fact that a subject which formed the main topic of discourse at the Congresses of London and Copenhagen should have been dealt with at Washington, in one of the general addresses, in an antagonistic spirit. Bacteriology, and the promise it holds out for prophylaxis, have been a chosen theme by many writers and speakers on medical subjects for some years past; and perhaps it is only right that opportunity should be given for the declaration of opposite views. Professor SEMMOLA undertook this task at Washington. His address was eloquent, and abounded in wise and witty sayings. It was based upon the requirements of the logical methods of science, and its aim was to decry the pursuit of bacteriology, which he likened to the "systems" that in olden time dominated the medical world. The comparison was, to be sure, hardly a just one, for the ancient systems were reared on theoretical reasonings, and the application of bacteriology to pathology is grounded on observation. Nevertheless, Professor SEMMOLA thinks we are being led astray, and are following blindly a path which can only lead to disaster and discomfiture. It may, then, be worth while to follow his argument in order to ascertain how far his conclusions are worthy of acceptance, and to what extent his warnings should be regarded.

That the aim of the physician is the cure of disease, and that the true test of medical progress is the great or small number of patients rescued from death, are propositions which may be taken for granted. It is true also that the methods of investigating medical problems differ from those formerly employed. Observation has replaced introspection, and the study of the phenomena of life in natural and morbid conditions forms the groundwork of modern medicine. This is the experimental method which Professor SEMMOLA rightly holds up to admiration, with its three components of (1) observation, (2) the formation of hypotheses, and (3) their verification. But owing to the diversity and complexity of the problems involved, and the ill-judged haste with which discoveries are declared, the actual progress towards the ultimate aim—that of assuring medicine a position among the exact sciences—is very halting and slow. Medicine, said Professor SEMMOLA, like other sciences, is not concerned with the discovery of the first cause; it seeks only to determine the physical or chemical conditions in which phenomena are manifested, in order that these may be controlled at will. These phenomena are the functional disturbances or symptoms of sickness. Their physical and chemical conditions are the natural causes of sickness; and the physician's aim is to artificially modify these conditions in disease so as to reproduce normal states, and to bring about a return to normal functions. Now, all this may be true, but it confines the application of the experimental method within the limits of the animal organism, the derangement of which constitutes disease. Professor SEMMOLA holds that it must be confined within this orbit, that outside of it we encounter only empiricism and ignorance, and therefore it is that he believes the prevalent pursuit of bacteriology, in its endeavour to introduce biological facts to the explanation of disease, is erroneous. He equally arraigns cellular pathology, condemning it also because its attractiveness has led to a disregard of the proper course to pursue in investigating disease.

Bacteriology, he tells us, is but a revival of an old doctrine of interpenetrating germs, and he wonders at the lack of caution possessed by those who are daily publishing their discoveries of new germs, and attempting thereby to revolutionise pathology. "Every clinician finds it indispensable to open at the side of his hospital ward a laboratory for bacterial culture. On one side of the hospital is a room for the cultivation of bacteria, and on the other is a room for patients, and the expenses of the first are often greater than the allowance of food for the second." Such sarcasm is hardly merited. It is no doubt true that many premature discoveries have been made, and that inoculation for the cure of diseases has been advocated with irrational enthusiasm, based on the results of experimental research with bacterial cultures and the knowledge of the conditions of bacterial life. But the method of inquiry should not be condemned for the over-zeal of some of its followers. In spite of the luxuriant crop of observations upon pathogenic bacteria, the subject is yet in its infancy, and its future is probably much more fruitful than can be at present conceived. We can only arrive at truth by devious ways. There is no wide and open path towards it; its approach is beset by the pitfalls of false generalisation. Nevertheless, the labours of the bacteriologist ought not to be discouraged. Any additional light which can be thrown upon the nature of disease through his observations should be welcomed. Professor SEMMOLA, however, has done some service in pointing out a danger attending the pursuit of bacteriology as a special study—viz., that too much attention may be given to the morbid germ and too little to the nature of the soil in which it is implanted and where it flourishes. Because a microbe is discovered in a disease, it does not follow, he said, that it is the cause of the disease rather than its effect. In osteomyelitis or endocarditis the soil must be prepared by injury before the microbes can attack the

cause summaries published of it have incorrectly conveyed the views of the author as to the influence of hereditary taint. The presidency of Lord BASING, who, as Mr. SCLATER-BOOTH, held office as President of the Local Government Board, gave especial importance to this year's gathering, and he took occasion in his inaugural address to take stock of the present position of State Medicine, and to review its progress since the date of the Royal Sanitary Commission of 1869–71. The progress, he explained, had been great, and he admitted that it was largely due to the activity, knowledge, and intelligence of the "able body" of "medical experts" by whom the Minister of Health was surrounded. Their advice, he said, "is constantly needed and eagerly sought" by local authorities, whereas their published labours have formed text-books and scientific treatises which have been of "service to the world at large," and have been accepted as "finally authoritative." All this appears at first sight to be matter for satisfaction, but Lord BASING proceeded to hint that the relation between the medical profession as a whole and the medical experts in question should now be reversed. Apparently he feared that if things remained as they hitherto have been, and still are, more public money might be devoted to the promotion of public health; for, referring to the health department of the State and the public, he would have induced his hearers to believe that they represented "two powerful currents of sentiment and opinion running counter to each other," and that a continuance of the present state of affairs would involve "more public expenditure." Hence he demanded "how long the medical profession were to be satisfied to sit at the feet of Gamaliel in Whitehall"; and, reminding his audience that local officials had now been appointed to carry out the system of State medicine, he asked to what extent the profession would continue "to accept without question the inquiries and reports produced at the public charge" by the medical inspectors of the central authority. He then went on to urge more trust in local organisations than in a central bureau.

We so entirely agree with Lord BASING as to the desirability of extending the principle of local self-government as regards almost all the matters dealt with by the Local Government Board, that we regret the strong financial ring that marred his utterances. Both in matters relating to health and to pauperism far more trust in local authorities and local officers, and far less central interference, are needed; but we cannot understand why a central organisation which has, according to Lord BASING, hitherto done work which has been of value to local officers, and indeed to the whole world, should not go on doing similar work, and, providing that work be of the same character as heretofore, retaining the confidence which he says it has secured up to the present date. We have more than once called attention to the needless way in which central inspectors are occasionally used to investigate conditions and diseases that have no more than a local interest; but the fault lies largely with the local authorities, who clamour for so-called "independent" inquiries, and if these are not at once granted they move someone in the House of Commons to bring pressure upon the central authority to do work which their own medical officers of health are quite capable of doing themselves. The truth is that a body of local experts is being gradually created throughout the country, who should receive such confidence from their local authorities that there would be no need to run for help to a central body wherever an emergency takes place. But it is altogether another matter with the subjects that Lord BASING had in view. He evidently aims at preventing extension of work which, though it may produce "scientific treatises" which admittedly go forth as authoritative to the most distant parts of a world-wide empire, tends to involve "more public expenditure." Now, it is precisely this class of work that can alone be done by a central authority, and if ever there was a period when the continuance and development of such work were wanted it is the present time. What would have been the present state of the metropolis as regards small-pox had it not been for the proof which these "experts" exhibited that our small-pox hospitals, largely erected under the Poor-law system which Mr. SCLATER BOOTH superintended, were spreading disease all around them? And only a month or two ago information from the same source opened up a new prospect for the prevention of scarlet fever, which it is believed by many to have been traced back to disease in the cow. The profession and the public alike have a right to demand that such matters should be sifted to the bottom, and it is clearly the duty of the Government to do this. In fact, many of the most important advances in public health have been facilitated by investigations, not limited to single sanitary areas, but extending over the whole kingdom; and these inquiries, though they can only be properly carried out by the co-operation and aid of local medical officers of health, cannot be brought to a successful issue by anyone whose jurisdiction is limited within the bounds of a certain sanitary area.

The proceedings of the Sanitary Institute themselves gave a pretty clear indication of the general feeling in this respect. Dr. ALFRED CARPENTER, dealing with the question of "public expenditure," showed what enormous results had already been brought about at a very small cost, and then pointed out that whilst millions were spent on life-destroying agencies, something less than £2000 a year were voted for scientific research in connexion with the prevention of disease; and other members brought before Congress subjects which have been largely illustrated and advanced by the scientific work which is carried on by the department over which Lord BASING once presided. This was notably the case in Dr. PARKES' admirable paper on Water Analysis, in which he showed, in continuation of the labours of the medical department of the Local Government Board, what is the true value of a chemical analysis in the case of waters which are regarded as having been potent to produce disease. And, on the matter of the acceptance without question by the medical profession of the views of Whitehall experts, the Institute itself, again, can show amongst its list of members many who would never be a party to the mere blind acceptance of the views of any person who had not so dealt with his facts as necessarily to carry conviction. The views as to the diffusion of infection from small-pox hospitals were at first subjected to able criticism from local officers of health and others, and their criticisms had the desirable effect of leading to renewed investigations and the production of further proof by the central authority. At the present moment, moreover,

THE LANCET.

LONDON. SATURDAY, OCTOBER 1, 1887.

IT is doubtless possible to obtain a knowledge of any branch of science or art by steady application and persistent endeavour without the aid of oral instruction, but unless there is to be a prodigious waste of strength and time, there must, particularly in the case of applied science, be teaching, and, therefore, teachers. Both are necessary in a very practical sense in the study of medicine. So much of the knowledge to be gained consists in doing the right thing in the right way—in a word, *expertness*—that if the medical student were to set about the attainment of his object without the assistance of instructors, he would need to possess almost all the energy and qualifications of a discoverer; and only those who were thus specially gifted could hope to succeed. It follows that very much must depend on the quality of the teaching and the skill of the teacher. We sometimes doubt whether this is adequately realised. It would seem to be supposed that if only a certain amount of information is served out to students—as a ship's cook serves out the rations of a crew,—it is their own fault if they do not digest, assimilate, and derive intellectual nourishment from, the food supplied. May we be permitted to suggest that something at least may depend on the cooking. Not a little of the junk and biscuit with which the student of medicine is regaled requires to be carefully prepared, and would be all the better for a little careful cookery and decent serving; and he has a right to expect knowledge and dexterity on the part of his teacher, and something more than the rude hacking of joints and ladling out of soup with which he is too commonly served. It is not, perhaps, to be expected that the lecturer at a school of medicine should be an orator, or his delivery equal to that of a popular speaker, but it is unreasonable to suppose that young men, not wholly ignorant of the ways of lecturers in other branches of knowledge, can be interested or even contented with dreary drone and confused discourse. A very little effort on the part of any man of ordinary ability would enable him to master the difficulties of a clear and fairly animated style of address to his classes. The truth is that this matter of delivery is scarcely even thought about. Lecturers are not chosen for their skill as oral teachers, nor do they bestow any pains on this particular phase of their discharge of professional duty. It suffices them to know their subjects, and to rehearse in the lecture-room so much of their knowledge as may be required by the curriculum. This done, the student must take his chance of being instructed; and as regards his preference for a good style of delivery, that is not to be thought of. Now we contend that those who reason thus fail in their performance of the important task entrusted to them.

A chair in any branch of medicine ought to be deemed a post of distinction and usefulness, for which special fitness is demanded, and upon which both skill and energy should be bestowed. It is not enough to give utterance to good matter; the utterance ought to be worthy of the material to be communicated. It is not true that "good wine needs no bush." There never was a more senseless saw than that. If the wine be good there ought to be a great deal of bush, and it should be hung out conspicuously, so that those who must needs buy wine may be enabled to procure the best. Those who have had the privilege of "sitting under" lecturers who really knew how to lecture, and did not consider an audience of intelligent young men unworthy of their consideration, look back with pleasure through life on the fact that they gained a good deal of information with especial ease; while those who have not been so happily placed cannot but resent the neglect of which they were the victims. It is impossible to acquit the medical lecturers, as a class, of blame in this matter. There is no reason why a lecture on any subject in medicine, surgery, physiology, anatomy, pathology, chemistry, or what not, should be dry and irritating, instead of entertaining and attractive; and we will go the length of saying, without a moment's hesitation, that when a lecture does not charm the intelligent student it must be because the lecturer has failed in his performance. Students of science do not want to be amused, and there is scarcely, we think, a more grave mistake than the attempt to enliven a discourse on any serious subject with so-called pleasantries that offend good taste, and provoke a smile rather in contempt of the speaker than in homage of his wit; but, with perfect dignity, befitting the matter, the manner of an address may be easily made interesting in place of being dreary.

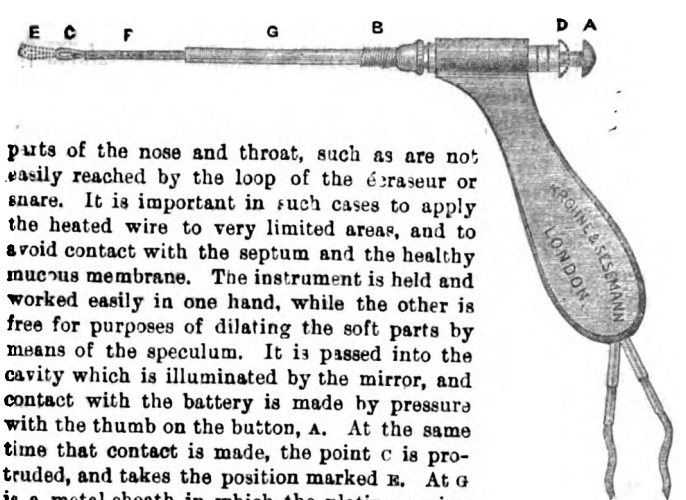
In short, lecturers in medical schools ought to be good speakers, with voices that do not jar on the ear—and no voice need offend if it be properly managed,—pleasing manners of speech, and the skill that consists in the knowledge of a spoken language, and power to use it properly. Elocution is a necessity of the function of oral teaching. The student is not *taught* when badly chosen words are either drawled in his hearing or hurled at him. If teachers would only give heed to the fact that teaching implies communicating knowledge to the student, not simply placing it within his reach, and would give time and attention to the acquisition of an agreeable style of delivery, they would not only do better work, but reap their reward in that popularity with their classes which establishes a bond of union between the teacher and the taught, that neither time nor distance ever completely severs in after-life. The student who enjoys his lectures as an intellectual treat, and feels that he is taking in knowledge in a time-and-trouble-saving way, will not quickly forget the boon or its giver when he becomes a practitioner, and it will rarely happen that the revered teacher is not also the natural referee in moments of difficulty for the pleasantly and successfully taught.

THE meeting of the Sanitary Institute of Great Britain at Bolton must be regarded as a substantial success. It will have tended to a more widespread interest in the important subject of public health; it has led to the preparation and publication of a number of very valuable papers, and some of the discussions on these have been marked by considerable learning. One of these papers—namely, that on Preventive Medicine by Dr. RUSSELL REYNOLDS—we publish to-day, and we would the more call attention to it be-

Digitized by Google

numerical method, and is orderly in his arrangement of facts. There is no attempt to discuss any of the problems of surgery, but merely to state the results of surgical experience. We learn in the preface that the book has been written for the student "when first entering on the study" of surgery. For such readers it is, in our opinion, singularly ill adapted. Put into such hands the book would be nothing more or less than a "cram." Such men want a clear discussion of the great principles of surgical pathology and therapeutics, and not a synopsis. The true use of this book is for men at the end of their student career, when, having firmly grasped surgical principles, they want to freshen their memories on the details of surgical injuries and diseases. Such men will find it a very useful help. We have noticed a few errors which have escaped Mr. Walsham's critical eye, but for a book of the kind the whole is done so well that we hardly like to refer to them.

A Handbook of Diseases of the Skin, with especial reference to Diagnosis and Treatment. By ROBERT LIVEING, A.M. and M.D. Cantab., F.R.C.P. Lond., &c. Fifth Edition, Revised and Enlarged. London: Longmans, Green, and Co. 1887.



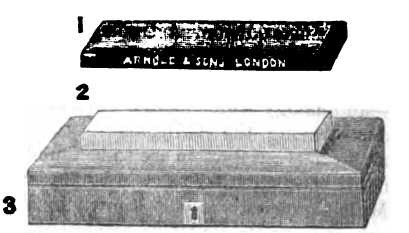
DR. LIVEING'S little Handbook has deservedly found favour in the eyes of the profession, alike from the reputation and experience of the author, his excellent teaching, the clear, easy style in which the work is written, and the judgment and discrimination with which the matter is selected and arranged. In welcoming another edition, we may content ourselves with pointing out that the author has successfully striven to ensure that there should be no falling off in merit. Many articles have been rewritten; the whole book bears marks of careful revision; separate articles have been added on Nomenclature, Classification, and Medicinal Eruptions, and a number of new ones introduced on some important diseases. We have read the new edition with much pleasure.

New Inventions.

A NEW GALVANIC CAUTERY INSTRUMENT,

FOR USE IN NARROW CAVITIES, AND ESPECIALLY FOR THE TREATMENT OF INTRA-NASAL GROWTHS.

THE instrument delineated in the woodcut was designed by me for the application of the cautery to the deeper parts of the nose and throat, such as are not easily reached by the loop of the écraseur or snare. It is important in such cases to apply the heated wire to very limited areas, and to avoid contact with the septum and the healthy mucous membrane. The instrument is held and worked easily in one hand, while the other is free for purposes of dilating the soft parts by means of the speculum. It is passed into the cavity which is illuminated by the mirror, and contact with the battery is made by pressure with the thumb on the button, A. At the same time that contact is made, the point C is protruded, and takes the position marked E. At G is a metal sheath in which the platinum wire, F, is made to advance or recede. As soon as the cautery has acted sufficiently, pressure is removed from the button, A, when the point E again recedes to its position, C, and at the same time, contact being cut off, the wire speedily becomes cool, and the instrument can then be removed without danger of cauterising the healthy parts. It is sometimes desirable to cover the part of the instrument between B and C with a quill, and thus still further protect the parts (the end of the quill at C being open either laterally or terminally, and thus allowing the heated point to protrude and recede within a non-conducting channel). This instrument can be used with a three or four cell bichromate battery. When used after the application of cocaine to the nostrils there is seldom any bleeding, but if bleeding occurs the instrument must be withdrawn, and only again used after the blood has ceased to flow. When the cavity operated on is wide, a shield in the form of an ivory tube can be screwed on to the metal at B, but in narrower cavities a crowquill slipped over this part acts very well, and forms a very good means of protecting the mucous membrane from being scorched. This apparatus is made by Messrs. Krohne and Sesemann. I have found it very efficient, more especially for the treatment of polypus nasi after the bulk of the growths has been removed by the snare or galvanic écraseur.



W. SPENCER WATSON.

AN IMPROVED FORM OF DISSECTING CASE.

IT has often occurred to me that the usual form of dissecting case is scarcely as practical as it might be. I have therefore suggested some alterations and additions to Messrs. Arnold and Sons, of West Smithfield, who have carried out all my suggestions. They are as follows:—

1. The substitution of four for the six knives generally furnished. Of these four, three are made much smaller than usual, the ordinary pattern being too large for fine dissections until worn down. 2. The spring in the forceps is made specially weak, as otherwise the fingers soon get cramped and fatigued. 3. An extra pair of hooks is supplied, for with a single pair it is impossible to get counter-tension. Moreover, as hooks are easily borrowed, a small ivory indicator is affixed to the connecting ring for identification. 4. To prevent the bore of the blowpipe from becoming blocked a clearance plug is provided, which fits the tube and is kept inside until the former is wanted. 5. A small fine pair of scissors replaces the two large pairs generally supplied. 6. A card of ligature catgut occupies a small pocket inside the lid. 7. A good oilstone is fixed on the outside of the lid of the case, protected by a wooden cover. This enables the dissector to keep his knives in order without moving from his seat or having to procure a stone. By the subtraction of the two knives and extra pair of scissors, the price remains the same or nearly the same as in the old form.

Reviews and Notices of Books.

A Treatise on the Theory and Practice of Medicine. By JOHN SYER BRISTOWE, M.D. Lond., LL.D. Edin., F.R.S. Sixth Edition. London: Smith, Elder, and Co. 1887.

WHEN a text-book has gone through so many editions as this one, it has passed beyond the pale of criticism. Its excellence and its value have received the Hall mark of the approbation of students and teachers alike. All that can be reasonably demanded of the author who has thus earned the reward of much patient labour is that he take care to keep his work abreast with the progress of science. And Dr. Bristowe is the last who would allow his teaching to fall behind, so that no new edition of his book—which has now been before the world for rather more than ten years—appears without some emendations and additions. The present edition differs from its forerunner in containing a concise account of Pasteur's preventive treatment of hydrophobia, of which he says: "It is scarcely now open to doubt that Pasteur has discovered a method of inoculating with attenuated or modified virus by which not only unprotected animals may be rendered insusceptible of hydrophobia, but such as are already in the incubation stage may have the progress of their malady permanently arrested." The chapter on Skin Diseases has been amended, and we all know that Dr. Bristowe is an authority in that branch of medicine. The subject of Recurrent Palpitation, first described by the late Dr. Cotton, is introduced and faithfully depicted. It is noteworthy that in severe cases this functional derangement of the heart may lead to all the mechanical effects of organic disease, being itself doubtless the initiation of structural change in the heart wall. Raynaud's Disease is another subject which has been much studied of late years, and the student will be glad to find so clear and faithful a description of its phenomena as is contained in this edition. Actinomycosis and mycetoma are described in the same section, the author pointing out the close resemblance that exists between these two parasitic affections—an analogy which cannot fail to strike the reader as accurate. Among the additions to the section upon Diseases of the Nervous System are to be found articles upon multiple neuritis, congenital tabes dorsalis, and Thomsen's disease. Multiple neuritis is best known in alcoholic paralysis; but there is, as Dr. Bristowe points out, an idiopathic form of the affection; and he also attributes the nerve symptoms of beri-beri and of diphtheritic paralysis to the same lesion. In point of fact, everything goes to show that toxic and toxæmic affections of the nervous system involve the peripheral rather than the central organs; and the category of instances in which multiple neuritis occurs is constantly increasing. It would seem as if neurologists, having wellnigh differentiated all the types of central lesions, were now exploring the peripheral system. It is unnecessary to dwell at length upon the main features of Dr. Bristowe's work. It is acknowledged to be remarkable for its accuracy and fidelity to clinical and pathological facts. As a minor point in which some improvement could be made, we might indicate some of the woodcuts illustrative of the histology of new growths. Those, for instance, representing tubercle and gumma are by no means up to our present knowledge of the minute structures of these formations, and we fail to see any advantage in reproducing Virchow's well-known diagram of a tubercle, which is certainly too ideal to be of practical utility.

The Prevention of Consumption. By C. CANDLER, Melbourne. London: Kegan Paul, Trench, and Co. 1887.

IT has been often pointed out that Koch's discovery of the tubercle bacillus has modified our conceptions of pulmonary phthisis, but it has also been difficult to harmonise the new doctrine with numerous well-established facts in the etiology and history of the disease. Mr. Candler has undertaken this task by submitting Koch's views to searching criticism, and proffering a new theory regarding the relation between the bacillus and mankind. He has done this in an interesting and attractive manner, with the main object of explaining the most rational way for preventing the development and spread of consumption. The key-note to his argument is to be found in his rejection of the hypothesis that the bacillus tuberculosis is a pure parasite, without vitality except at blood heat. For this view he substitutes the doctrine that the bacillus is a freely growing organism, which flourishes under certain conditions outside the body, and that its implantation in the human subject is a matter of accident rather than an essential condition for its maintenance. He believes that the botanical side of the matter has been inadequately considered, and that in consequence an erroneous view of the true nature of the bacillus has gained ground. In other words, he would rank tuberculosis with the malarial group of diseases rather than with the strictly parasitic; and he thus bridges over the difficulties that arise in our conception of the nature of this disease when we are confronted with the questions of heredity, environment, and soil, which have so long been accepted as playing a considerable part in its etiology. Given, he would say, certain favourable external conditions, and the bacillus will flourish, so that those individuals who are subjected to the same conditions are liable to become attacked by it. According to him, the chief of such conditions is the absence of sunlight, the influence of which upon the vitality of bacterial organisms was first made known by Downes and Blunt. The reason why tuberculosis is inherited and clings to family stocks is, on this view, to be found in the living of the same family in the same abode; and he draws a disheartening picture of the family country house, with its darkened rooms, especially the sleeping rooms, as powerful influences in determining the prevalence of phthisis. It follows, then, that the most appropriate means for preventing the spread of consumption lies in the free admission of light and air into dwelling-houses; and, in the case of those with inherited taint, their removal from the baneful surroundings in which they were brought up. It is needless to point out that these principles have been advocated for a long time by physicians, and by none more strenuously of late than Dr. Weber in his Croonian Lectures. Our author, too, has adopted very largely the views respecting the nature of phthisis which were enunciated a few years back by Dr. Andrew, also at the College of Physicians. There is no doubt a good deal to be said for them, but Mr. Candler is, like all enthusiasts, somewhat too hopeful of the good effects of the adoption of his plan of "sun-prevention." And, unfortunately, in the present day the realisation of his plan is absolutely impossible in our overgrown cities. Still, he has done good service in directing attention to the hygienic importance of the sun's rays, and has presented a thoughtful essay upon a great problem, which we trust may be widely read.

Surgery: its Theory and Practice. By WILLIAM JOHNSON WALSHAM, F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital; Surgeon in charge of the Orthopædic Department and Demonstrator of Practical Surgery at St. Bartholomew's Hospital; Surgeon to the Metropolitan Free Hospital; Examiner in Surgery to the Society of Apothecaries. With 236 illustrations. London: J. and A. Churchill. 1887.

THIS is one of Messrs. Churchill's "Students' Guide Series," and is not intended to displace any of the larger Manuals of Surgery. It is, rather, a brief epitome of surgery, and as such is very good. Mr. Walsham writes clearly and concisely. He freely avails himself of the aid of the

Digitized by Google

She had given birth to her sixth child while on the way to the hospital; and when she arrived under the care of the police, about forty minutes later, the placenta had also been expelled and the uterus was small and well contracted. It was impossible to obtain any details regarding the labour. The patient was, however, in a very weak condition, pulseless and cold, and vomiting occasionally a small quantity of mucus and clear yellowish fluid with a spirituous odour. Some whisky had been given to the patient before her admission.

Hot bottles were at once applied to the feet; a hypodermic injection of sulphuric ether (ten minims) given; and also, by the mouth, spirit of sulphuric ether and aromatic spirit of ammonia. To allay the vomiting a mustard poultice was applied to the epigastrium, and spirit of chloroform and compound tincture of cardamoms given internally. The vomiting soon ceased, and the patient's strength rapidly improved. Stimulants given by the mouth were continued during the day in decreasing doses. Beef-tea and gruel were given as food. Twelve hours later the patient was feeling and appearing much better.

During the following two days (May 23rd and 24th) the treatment of the patient did not differ from that of the others in the wards, and she appeared to be doing well. On May 25th the patient was noticed in the morning to be perspiring very freely, but as other patients were also perspiring more freely than usual, and the day was very close, no special attention was paid to the fact.

May 26th (fifth day).—At 4 A.M. the attention of the night nurse was drawn to the patient by something unusual in her expression. On inquiry if anything was the matter, she gave a negative answer, but her articulation was clearly defective. Previously to this, no unusual symptom, convulsions or otherwise, had been observed. The house-surgeon was immediately called, and on seeing the patient noticed that she had a dull, vacant expression. She put out her tongue in answer to a request that she would do so, but would not speak at all. No signs of paralysis were observable except those of defective articulation and the involuntary passage of urine. The heart was examined, but nothing abnormal detected.—9.30 A.M.: Patient now answers questions, but it is difficult to understand what she says on account of defective articulation. The muscles of the left side of the face are noticed to contract when the patient attempts to smile, but those of the right side remain uncontracted except the orbicularis palpebrarum. The tongue on protrusion is now pushed to the right side. The pupils are equal, and both react slightly to both light and accommodation. The power of both arms, as tested by asking the patient to grasp the observer's hands, is not normal; they seem to be equally weak. The power of the legs is also rather diminished. The temperature has at no time since delivery been abnormally high. The heart has again been examined, and no abnormality detected.—11.30 A.M.: The paralysis of the muscles of the right side of the face is now less marked. Patient seen by Dr. Sloan, who ordered that the child should be weaned at once, and that food of a more stimulating sort than that usually allowed in the wards should be given—beef-tea, soup, gruel, milk, and eggs.

27th.—Patient slept very well last night. There is to-day some control over the passage of the urine. The power of articulation is much the same as yesterday. In pronouncing her name (maiden) she says "Ididy Dada." The right arm and leg are to-day decidedly weaker than the left corresponding limbs; the latter are stronger than yesterday. The urine was examined; there was no albumen. The lochia are this morning absent, and the temperature a little raised, being about 100° F. The heart was once more examined, but no abnormal sounds heard. The pulse being rather weak, Dr. Sloan ordered five minims of tincture of digitalis and five grains of carbonate of ammonia, to be given every three hours; also that the patient should have cream of tartar water as a drink.

28th.—Temperature 100°; pulse 93. The lochial discharges have reappeared since last night; at midnight the napkin was saturated with a bright-red and slightly fetid discharge. A warm antiseptic vaginal douche was ordered to be used every four hours. Patient takes her food well and sleeps well. The bowels have not acted since the seizure two days ago, and an enema was therefore ordered. The bladder is now under control. Articulation is rather better, but not the power of the arms, and the tongue on protrusion is still much deviated from the middle line.—4 P.M. (note by Dr. Sloan): Pulse 120; temperature 101·8°. The uvula is drawn slightly to the left side. In pronouncing her name the patient now says, "Idiby Dath." The grasp is stronger in the right hand than yesterday. During the effort of grasping with the hands the face is drawn slightly to the right side. The breasts are firm and tender, but not enlarged. Only a clear fluid exudes on pressure. No milk has been drawn during the last forty-eight hours. The abdomen is somewhat full, but there is no tenderness; the uterus cannot be felt with moderate pressure.—7.30 P.M.: The lochia are no longer fetid. Since the enema was given the bowels have twice acted copiously.

29th.—Pulse 120; temperature 100° F. Patient slept well last night, and continues to take her food well. The arms are decidedly stronger. She was ordered by Dr. Sloan a tablespoonful of the following mixture every four hours: Carbonate of ammonia, one drachm; tincture of nux vomica, thirty-six minims; tincture of cinchona, three drachms; tincture of orange, three drachms; water to six ounces. The previous mixture was stopped.

30th.—There is decided improvement in the power of the affected muscles, and in the distinctness of articulation. Temperature normal.

June 3rd.—The patient continues to improve. The above mixture was stopped, and the following ordered, since she continues anæmic: sixty-four minims of liquor arsenicalis, sixty-four grains of citrate of iron and ammonia, and infusion of calumba to four ounces; two teaspoonfuls thrice daily after food.

7th.—Patient now names herself quite distinctly, "Elizabeth Alston." The paralysis of the right side of the face is still perceptible, although not at all well marked. The tongue is less pale. There is no difference in the grasp of the two hands as regards power. Patient rose last night for the first time. There is in walking no dragging of the right leg to be noticed.

8th.—Patient rose again this morning, and after doing so felt rather fatigued.

11th.—The paralysis of the right side of the face is but slightly marked, and improvement continues. The heart has been again examined several times, by Professor Leishman among others, and no abnormality of the cardiac sounds discovered.

13th (twenty-third day since delivery).—The paralysis has entirely disappeared, and the articulation is perfect. There is no abnormal cardiac sound to be heard even after the patient has exerted herself. She was dismissed to-day.

Remarks by Dr. SLOAN.—It may be impossible to decide with certainty whether this was a case of apoplexy or of embolism of the left middle cerebral artery, but the following are reasons for deciding in favour of embolism. There was no convulsion and no unconsciousness; the patient is young, and there is no evidence of disease of the kidneys or of the arteries; the hemiplegia was gradually developed, was never complete, and it speedily passed off; the circulation was sluggish, and the blood, on account of the puerperal state, was in a condition to coagulate readily. Query: Why is embolism on the left side of the heart, without cardiac disease, so uncommon in the puerperal condition, and puerperal embolism on the right side so far from uncommon? If this is, as seems most probable, a real case of cerebral embolism in the puerperal state without cardiac valvular disease, it is, so far as can be ascertained, the first case of the sort reported. The treatment consisted of cardiac tonics and alkalies.

THE NEW CORONERS ACT.—The Coroners Act, 1887, which has just been issued, makes several alterations in the law affecting coroners throughout England, the Act not applying to Scotland or Ireland. "Viewing the body" is still to be part of the procedure at inquests, the new measure explicitly stating, "the coroner and the jury shall, at the first sitting of the inquest, view the body." Attention has been given by the Legislature to the manner in which coroners are to be elected. Electors are not now qualified to vote at such elections unless they take an oath at the polling booth, declaring they are freeholders, and possess land in the county in which they vote. The oath for swearing coroners' jurymen having varied in different counties, the statute provides a standard form of oath to be administered. The extent to which a juror may be fined has been raised from 40*s.* to £5. By the operations of the new statute about thirty-three Acts of Parliament, many of them of a quaint nature, dating as far back as Edward III., have been wholly or in part repealed.

during the night; profuse sweats; œdema of abdominal walls; tympanites; some ascites.

24th.—The patient was placed under an anæsthetic, and an oblique incision made through the abdominal walls, about three inches in length, parallel to, and an inch and a half below, the cartilages of the lower ribs, and dividing the rectus abdominis. The peritoneum was firmly adherent. A trocar was then inserted, and was followed by an escape of pus. A grooved director having been passed in, the abscess cavity was laid freely open. Sixteen ounces of pus, thick, grumous, but not offensive, poured out. The cavity was very irregular in outline, though its walls were smooth; in size it was about that of a cricket ball. Two drainage tubes, fastened side by side, were fixed by means of a silk suture, and the wound dressed antiseptically.

25th.—The patient passed a good night, but had some pain. Temperature 97·8° in the morning; pulse 102°. She had vomited twice during the night. Legs very œdematous. The wound was dressed, pus pouring out on removal of previous dressing. Urine: sp. gr. 1022; acid, with the faintest trace of albumen.

27th.—Wound dressed; discharge still profuse; wound looking healthy; abdomen tympanitic; legs still œdematous. Temperature normal; pulse 96. Complained of a little pain in the right side.

May 5th.—The general condition had improved; there was still a copious discharge of pus, but the cavity and orifice of the wound had contracted very much. The tympanitis had subsided and the œdema of legs was much less. The patient slept and took nourishment well. Temperature normal; pulse 96. From this date the patient gradually improved and made a perfect recovery.

Remarks by Mr. HARRIS.—This case of a large solitary abscess of the liver is interesting, more especially because of the obscurity of its origin. The idea of a "tropical" abscess may be at once dismissed, the only foreign part in which the patient had resided being Boulogne, and she had never had dysentery or any disease of the rectum. A question which perhaps is worthy of consideration is that of gummata, undergoing softening, becoming fused together, and thus forming one large abscess. It is true the patient had had what to all appearances was a gumma on the lower extremity, but this had healed under treatment, and it seems highly improbable that whilst the good effects of potassium iodide were manifesting themselves in one part of the body gummata should form and eventually break down in another. It is not likely that any local cause, such as an impacted gall-stone, could give rise to such a result without pain and without jaundice; it is far more probable that the abscess was due to the suppuration of some pre-existing though undiscovered cyst, such as a hydatid, although no cysts were visible in the fluid which escaped, and it is to be regretted that the fluid was not examined microscopically. With reference to the treatment, it would probably have been better not to have allowed so long an interval to elapse between the establishment of the presence of pus by the aspirator and the incision into the abscess cavity. Against any advantage gained by a more perfect consolidation of the layers of the peritoneum must be noted the further destruction of tissue and the greater accumulation of pus which took place during that time, and it seems probable that had the œdema and redness of the abdominal walls been taken as an indication that the peritoneum was adherent her recovery might have been accelerated. The œdema of the legs was probably due to pressure on the inferior vena cava by the inflamed liver tissue.

WINDSOR STATION HOSPITAL.

FRACTURE OF THE FIFTH CERVICAL VERTEBRA, WITH COMPRESSION OF THE SPINAL CORD; DURATION OF LIFE TEN MONTHS.

(Under the care of Surgeon-Major MYERS.)

PRIVATE S——, Grenadier Guards, a very strong man, aged twenty-three, weight 14 st., was admitted on July 3rd, 1886. He stated that whilst bathing in the Thames, near Windsor, he dived head foremost into shallow water (two feet), and was taken out almost immediately by some comrades, who noticed that his legs were completely paralysed, and he was at once conveyed to the hospital. When seen shortly afterwards, he was lying on his back, perfectly conscious, but devoid of sensation and motion in the lower part of the trunk and legs. Slight sensation was present to about the lower angle of the scapula, and there was some power of movement in both arms at the shoulder; respiration was entirely diaphragmatic; pulse slow and strong; the patient complained of no pain excepting at the back of the neck in the region of the fifth and sixth cervical vertebræ, and chiefly on the left side. He stated that while lying under water he knew he was quite paralysed, but held his breath, hoping that assistance might be sent him. Careful notes of the case have been taken by Surgeons Alexander, Sheldrake, and Carte, of the Brigade of Guards, but as its great interest rests on the unusual prolongation of life, a few comments only are needed.

Some days after admission the arms became motionless, excepting a slight power to raise the elbow from the side, and remained flexed. The sensation returned in the right arm, but it soon became apparent in the left arm as low as the elbow, and extending over the anterior surface of the radial half of the forearm, and at a later period in the tips of the thumb and first and second fingers. Over and above the shoulders there was marked hyperæsthesia. For many weeks bedsores were well kept in check, though continually threatening, but in course of time they formed in numerous places, especially along the under surface of the right leg, and even on the toes, where no pressure occurred. At a later stage the integument of the back became completely undermined and converted into a large sac, containing very offensive pus. This sac, by irrigation twice daily with disinfectants through the sacral bedsore, completely disappeared; and a short time prior to death the bedsores of the right leg had healed, and others over the scapulæ, elbows, and hips had nearly done so, and even the deep sacral bedsore had greatly contracted. Cystitis set in at an early stage, hastened probably by an acute attack of gonorrhœa, from which the patient was suffering on admission. This was completely arrested for a time by frequent irrigations with different disinfectants. Two months after admission the patient stated he could feel the flow of water from the irrigator into the bladder, and this regained some power, the urine being occasionally expelled with force, though unconsciously to the man. After some months slight reflex action of the leg muscles could be obtained by the galvanic battery and by tickling the soles of the feet, and tended to increase to the last. Latterly he began to raise both elbows to the level of his head, and flex the left arm sufficiently to enable him to touch his face with his fingers, but he could not bring the arms back to his side. Rotation of the head became quite free and painless, and considerable pressure could be borne over the seat of fracture without causing discomfort. The temperature rose irregularly till the evening of Aug. 16th, when it reached 103·2°; after that date it gradually became normal or subnormal, and, excepting occasional short and sudden rises, remained so until the last week. The action of the bowels from first to last remained involuntary. About the middle of April, 1887, his appetite, which had been surprisingly good, began to fail, the urine became fetid, vomiting set in, the bedsores began rapidly to reappear, and on April 28th urine ceased to enter the bladder. Vomiting then became incessant, and on May 2nd the patient died.

At the post-mortem examination the cervical vertebræ were removed. The kidneys were completely disorganised, the right one being almost entirely converted into one fetid abscess. The ureters were much dilated and thickened, and deeply stained. The bladder was also much hypertrophied and stained, and contained only a little fetid pus. There was nothing special to remark about the thoracic organs. The brain was not examined.

The following is a report of a sectional examination of the cervical vertebræ made by Dr. Silcock:—"The body of the fifth cervical vertebra has been crushed and somewhat displaced backwards, giving rise to a projection in the spinal canal. Opposite this projection the spinal cord is almost completely disorganised, evidently by the pressure exercised upon it."

GLASGOW MATERNITY HOSPITAL.

A CASE OF HEMIPLEGIA DURING THE PUERPERIUM.

(Under the care of Dr. SAMUEL SLOAN.)

THE following notes were communicated by Ernest Roberton, M.B. Edin., in-door house surgeon of the hospital, in a paper read before the Glasgow Obstetrical and Gynæcological Society.

Mrs. D——, aged thirty, was admitted on May 22nd, 1887.

Digitized by Google

occasion divided into two parts—viz., first about two ounces, being that passed at the commencement of micturition, and secondly the remainder. On every occasion that the urine was examined for six consecutive days it appeared to the naked eye to be normal; the only appreciable difference between the two portions was that the second part deposited a much larger proportion of mucus than the first. Microscopically, a few stray red corpuscles were seen, and these occurred far more frequently in the second part of the urine. On the first occasion, finding a small shred which was passed at the end of micturition, I placed it on a slide, and found that it was a small slough in which were embedded two ova of the bilharzia, and on every subsequent occasion I was able to find at least one or two ova, though the urine remained quite clear and pale. My evidence was given accordingly, and on this and other evidence the prisoner was convicted and dealt with.

Another observation of mine comes under this heading. At a necropsy performed for a coroner's jury, I reserved portions of the viscera for microscopic examination. The subject was a native; the case one of general disseminated tuberculosis; and it is possible that any appearance due to the presence of the bilharzia was masked by the tubercular ulceration of the mucous surfaces. On examining some of the sections of lung, I found groups of two or three ova embedded in the interstitial fibrous tissue. These ova varied in length from 0·95 to 0·12 mm.; and though not furnished with any very distinct spine, they corresponded exactly with those figured by Kartulis[3] as the ova of bilharzia occurring in the liver and kidney; and if they were really such, my observation is not unique, for Birch-Hirschfeld has seen the ova in the lung in sections prepared by Dr. Schieff Bey of Alexandria.[4] As, however, I have found them in the lung only, I have provisionally labeled the slides "Bilharzia (?)," for it is possible that future observations may show that the Distoma Ringeri also occurs on the Gold Coast.

Accra, Gold Coast.

CASE OF INVERSION OF THE UTERUS, WITH COMPLETE PROLAPSE.

By F. S. BARBER, L.R.C.P. LOND., M.R.C.S.

MRS. L——, multipara came under my care during the third month of pregnancy, complaining of inability to pass urine, together with a swelling at the vulva. On examination, I found the uterus large, prolapsed, and wedged at the orifice of the vagina. The prolapse was rectified, and the bladder relieved by the catheter. Afterwards I introduced an ordinary Hodge's pessary; this gave great relief, and prevented any further recurrence. She wore the pessary for a month or more, and was then able to dispense with its support. In June labour commenced, and was attended by my assistant, who found on his arrival that the passages were relaxed and dilated, together with a normal presentation. After a few powerful pains the birth of the fœtus was accomplished, but was immediately followed by a prolonged and very severe pain and bearing-down, which caused the whole uterus to become inverted and extruded through the vulva, with the placenta still adherent to the fundus. The patient became faint, the pulse almost imperceptible, and the body covered with a clammy sweat. I was immediately sent for, and arrived within a few minutes. Needless to say I was somewhat alarmed at the state of affairs, and proceeded at once to diagnose the cause. On placing my hand on the abdomen, I could detect no contracted uterus; but on examining the mass (which was literally in the bed), I made out an inverted uterus with the placenta still attached. I tried to reduce it through the vulva as it was, and partly succeeded, but was unable to reduce the inversion without first detaching the placenta; this I did, and, although the hæmorrhage was very profuse, I was able to replace it in a few seconds, but not without having to try twice. The general condition of the patient was most serious. She was insensible, pulseless, and the extremities cold. After lowering the head and applying heat to the extremities, she was able to drink some brandy-and-water, to which I added liq. ergotæ (one drachm). By degrees she gradually recovered consciousness, and was able to recognise friends. During this time I had kept my hand upon the uterus, and was pleased to feel it contract under my pressure; the hæmorrhage ceased, and the present danger seemed, as it proved to be, past. The after attendance on the case varied but little from ordinary cases, save that I was more anxious, and consequently more attentive. The uterus as well as vagina were syringed with weak Condy's fluid, and opium and quinine prescribed for ten days.

Remarks.—In the treatment of this case I had occasion to resort to two methods of reduction—viz., (1) by pressure of the closed hand direct to the fundus; and (2) by the pressure applied by the fingers at the sides of the mass—that is, on the lateral portion (in both cases I had my hand externally to support the abdominal wall); and it was with the latter method that I was successful. The hæmorrhage was hardly as profuse as a number of gaping sinuses would lead one to fear, but I should imagine a condition of semi-strangulation existed.

PADDINGTON INFIRMARY.

ABSCESS OF LIVER; OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. H. ELWIN HARRIS, B.A., assistant medical superintendent.)

A LARGE single abscess of the liver is so uncommon when not of the variety known as "tropical" that this case is of much interest. The remarks appended to the record are important; it is possible, however, that it may have been of pyæmic origin from the acuteness of its onset and the presence of a possible source in the sore on the leg, but the hepatic abscesses in that disease are usually multiple, and the satisfactory progress after operation negatives this view.

A. G——, aged forty-nine, unmarried, a cook, was admitted on Feb. 5th, 1887, suffering from a red, tender, fluctuating swelling on the inner aspect of the right leg, about three inches above the malleolus; she had had a slight injury to the leg before admission, but had noticed the swelling previously to that. An incision was made and a large slough discovered at the base, the edges of the incision being much undermined; the whole appearance was very suggestive of a gumma. Some sloughing of the tissues followed, but it began steadily to heal under ten-grain doses of iodide of potassium administered three times a day over a period of a month.

On April 8th, about 5 P.M., the patient complained of feeling very cold, and shivered. The temperature was found to be 104° and the pulse 120. This was followed by profuse perspiration, but she complained of no pain. The ulcer had now nearly healed, and there was nothing in its appearance which would suggest any explanation of the symptoms. On examination, there was tenderness on pressure over the hepatic region, but there was no enlargement either of the liver or spleen. Fifteen grains of sulphate of quinine were administered internally, and poultices of linseed and opium applied to the hepatic region.

April 13th.—Increased tenderness on pressure over the liver, the dulness of which extended to four inches below the level of the costal arch in the nipple line. No jaundice. The temperature had assumed a hectic type, rising to about 102° in the evening and falling to normal in the morning. Twelve leeches were applied over the hepatic region, and a pill of quinine and opium given every four hours. The ulcer of the leg had now quite healed.

17th.—Œdema and redness of the abdominal walls were present over the enlarged liver, and the aspirator inserted at this point drew off twelve ounces of thick fetid pus. The patient was much collapsed after the aspiration. Temperature 96°; skin cold and clammy. She complained of no pain, however, excepting on movement or pressure.

21st.—The patient complained of pain in the abdomen

Digitized by Google

vessels were caught up in time to stop free bleeding; they were tied with catgut; the oozing of blood was controlled. A large drainage tube was put in the whole length of the wound, and the edges of the wound were united by carbolised silk sutures. A Gamgee pad, oakum, and over this a bandage, were applied, and the patient was put to bed. As this man would have suffered had his opium been stopped, he was allowed to take enough to satisfy his cravings.—July 7th: The patient had a fairly comfortable night's rest, has no trouble in passing his urine.—July 8th: Has pain and fever. On the third day there was a good deal of swelling: the lower end of the wound looked unhealthy, and there was a sero-purulent discharge. Temperature 103°. The drainage tube was removed, the stitches at the lower end of the wound were cut to allow a free opening for discharge, and the wound was syringed out with 10 per cent. iodoform in glycerine. The patient complained of pain in both thighs near the pubes, no sign of any local trouble could be found there. On the sixth day he began to improve; though he gained ground slowly, there was no further cause for anxiety.—Aug. 2nd: The wound is healed, except a small sinus in the track of the drainage tube. The patient has had perfect control over his urine all the time, and is much pleased at the relief from pain which has been afforded him by the operation.

Remarks.—My patient is fifty-nine years old, and he is prematurely feeble from his opium habit. He is entirely relieved of the pain from which he formerly suffered, and has a good chance of freedom from the disease for the remainder of his life. Mr. Pearce Gould's operation has now been performed often enough to show that it is the operation most likely to prevent a recurrence of the disease. It is one that any surgeon can perform, and the hæmorrhage is easily controlled. The one point where this case differs from the operation, as performed by other surgeons, is the making of a new urethra prior to the removal of the penis. In performing a severe operation on an old man enfeebled by disease, it was a distinct gain to have no danger of any trouble about the urethra. The patient made a good recovery, and I hope that other surgeons will give this method of performing the operation a fair trial.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RETRO-ŒSOPHAGEAL ABSCESS.

By J. THEODORE RICHARDS, M.B., B.Sc.,
HOUSE SURGEON, WIRRAL CHILDREN'S HOSPITAL, BIRKENHEAD.

THE following case, which may be compared with one published in THE LANCET of Jan. 1st, 1887, p. 17, was communicated (by the permission of Mr. Knox) to the Birkenhead Medical Society last winter.

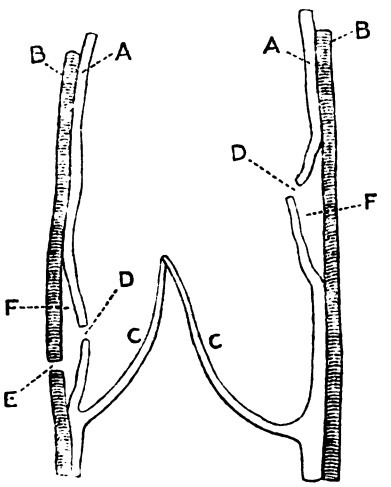
J. R——, aged three years, was admitted with Pott's curvature in the upper dorsal region of the spine. The last three months he had been unable to walk without supporting himself by the hands. The child held the head stiffly, inclined to the left side; complained of pain on any movement of the head, and on pressure over the spinal projection. The breathing was accompanied by a stridulous, husky sound, both in inspiration and expiration, and there was a loud, brassy, short cough. His father stated that he had noticed this character of the breathing for some months. The tonsils and pharynx were red and rather swollen. In the evening after admission the respiratory difficulty was more apparent; there was considerable recession of the lower part of the chest with inspiration; the stridor appeared to be partly nasal and partly laryngeal. There were no physical signs of disease in the chest. The child took food well, and the father stated that he had always done so. For the first four days that he was under observation the stridor varied somewhat from time to time. It was never great, and was almost absent when the child was undisturbed; it was sometimes more marked with inspiration, at other times with expiration. The respirations were 30 per minute. The inspiratory recession at the base of the chest continued in varying degree. There was never any hoarseness in crying or speaking, the voice being unaffected. The child swallowed both liquids and solids freely, without any sign of difficulty. No prominence could be detected at either side of the neck. There was no lividity of the lips or nails, and the temperature was about 100°F. On the sixth day after admission, with a rise of temperature, signs of pneumonia were developed, and the child rapidly became worse, with more cough and dyspnœa and the general aspect of broncho-pneumonia, which caused death two days later.

Necropsy.—The body was well nourished. Both lungs were adherent to the chest wall and diaphragm, and their lobes to each other; the lower lobe of the left lung was consolidated. There were numerous caseating and calcareous glands around the trachea. Behind the œsophagus, and closely adherent to it, was a soft fluctuating tumour, oval in shape, larger than a horse-chestnut, in front of the vertebral column, and connected with it. The œsophagus was with difficulty separated from the front of the sac, having been compressed between it and the trachea. The situation of the abscess was fully an inch below the level of the larynx; it projected slightly to the left of the vertebræ, and a smaller sac passed from it to the right. The walls were thick and well defined, and when incised about half an ounce of thick white pus escaped. Forming the back of the abscess sac the bodies of the seventh cervical and first dorsal vertebræ were found to be almost destroyed, and the front of the bodies of the following two dorsal vertebræ was also carious.

Remarks.—The abscess in this case was due to one of the common causes of retro-pharyngeal abscess—viz, disease of the vertebræ,—but was rare in its situation low down behind the œsophagus, and consequently out of reach from the mouth for diagnosis or treatment. As in the case reported by Dr. Turner (*loc. cit. supra*), due to another cause, there was a complete absence of dysphagia, which is usually a prominent symptom of abscess at the back of the pharynx, although the œsophagus was pressed upon, and through it the trachea, sufficiently to cause signs of obstruction to the respiration. This, however, had lasted for weeks without becoming urgent, and death was due to the attack of pneumonia. A tracheotomy wound would have been a little above the level of the abscess.

BILHARZIA HÆMATOBIUM IN WEST AFRICA.

By C. H. EYLES, L.R.C.P. & S. EDIN.,
ASSISTANT SURGEON, GOLD COAST COLONY.



THOUGH hæmaturia is not uncommon among the natives of the Gold Coast, there have been no observations, so far as I am aware, connecting this condition with the presence of the Bilharzia hæmatobium; and further, though the parasite is common enough in the north and south of Africa, Hirsch appears to doubt its being the cause of the endemic hæmaturia of the more central parts of that continent, and suggests Filaria sanguinis hominis.[1] Up to the present I have found the ova of the bilharzia in the urine of four cases of hæmaturia on the Gold Coast. One case was that of a European, who had become infected in Egypt in 1882; the others occurred at Axim amongst natives of the coast.[2] Of these latter, two came under notice in the ordinary course as patients, and the third furnished a neat case in medical jurisprudence.

In the case of Regina *v.* Bernasko, tried at the Supreme Court of the Gold Coast Colony, the prisoner was charged with "sending letters threatening to accuse of crime with intent to extort money." His account was that whilst resisting an attempt made by one E. H. to commit an indecent assault on him, he (E. H.) seized him by the penis and wrenched the organ, as a consequence of which he had been passing blood per urethram for three consecutive days; and both in his letters and in Court he appealed to medical evidence to corroborate his statement. Accordingly I was asked to examine the prisoner, and report on his case. Five days had elapsed since the alleged assault, and there were no signs of injury about the penis; there was no urethral discharge, and a No. 10 catheter passed in freely without obstruction. I decided, however, to examine the urine; and in order to determine whether or not any inflammatory products had their origin in the urethra, the urine was on each

[1] Handbuch der Historisch-geographischen Pathologie, Bd. ii., S. 206.
[2] My colleague, Mr. R. A. Freeman, has also found the ova in the urine of two cases in natives of the coast at Accra.

heart to be invested by blood clot. A small opening just sufficient to admit a probe was found in the posterior wall of the aorta at its junction with the left ventricle, and almost touching the point of attachment of one of the semilunar valves. On opening the aorta along the anterior aspect, the inner coat was seen to have been ruptured in a transverse direction; the rupture was abrupt, and ran almost completely round the aorta, the ends being separated by a quarter of an inch of apparently healthy inner coat. The inner coat was stripped off the muscular coat for about a fifth of an inch both upwards and downwards, and the space was occupied by a blood clot. The small opening already described in the outer coat and middle coat was situated nearer the ventricle than the primary rupture in the inner coat. No areas of fatty degeneration could be detected. The kidneys were filled with cysts, and an attempt was made to obtain a specimen of the urine, but

DIAGRAMMATIC SECTION OF THE AORTA.
A A, Elastic coat. B B, Muscular and areolar coat. C C, Semilunar valves. D D, Primary transverse rupture in the inner coat. E, Secondary rupture in the outer and middle coats. F F, Small dissecting aneurysm.

the bladder was empty. The other organs were apparently healthy. The valves of the heart were normal. (See diagram.)

Remarks.—This case may, I suppose, be classed as one of remote sequela of typhoid; the immediate sequela being the condition of the kidneys. No albumen was detected in the urine during the fever eleven months previously, but the urine was not again examined during convalescence. The history of the case and the appearance of the lesion leads to the belief that the ruptures in the coats occurred on two separate occasions, there being an interval of four days, during which a dissecting aneurysm began to form. The friends inform me that she had not been in good health since her attack of typhoid, and they also assure me that she was undergoing no greater exertion than a slow walk when the fatal rupture occurred. The patient did not mention any cause for the first attack of pain on the Monday.

F. E——, aged fifty-nine, male. The man had suffered for some months from occasional but slight pain in the cardiac region, the pain radiating into the arms. He had noticed lately that he became easily "out of breath." On the morning of death (Sunday), while in the watercloset, he was heard to vomit, and on coming out said he felt faint and would go up and lie down on his bed. An hour afterwards he was found there dead.

Necropsy.—The pericardium was distended with bloody serum, and the heart was invested by a blood clot. After great difficulty a very small valvular opening, running upwards and inwards, was found in the anterior wall of the left ventricle. The opening would only admit a small probe. The muscular substance was pale and very soft. Under the microscope the striation was faint, and there were numerous fat-globules. The mitral and tricuspid valves were normal. The aortic valves were atheromatous, and the coronary arteries had undergone extensive calcareous degeneration. The other organs were apparently healthy.

Remarks.—As in the preceding case, the slightness of the exertion at the time of the fatal rupture was remarkable, though, I believe, not unusual. Had an attempt been made shortly before death I hardly see how a diagnosis of acute idiopathic pericarditis could have been avoided. Since the occurrence of these cases it has been a question in my own mind whether many of the cases of acute idiopathic pericarditis which are recorded might not have been in reality instances of spontaneous rupture. This patient was a man of moderate habits except as regards tobacco. Though a keen man of business, he could not be termed of active habits.

South Hampstead.

REPORT OF A CASE OF AMPUTATION OF THE PENIS FOR EPITHELIOMA.

BY H. W. BOONE, M.D.,
SURGEON TO THE AMERICAN CHURCH MISSION, ST. LUKE'S HOSPITAL, SHANGHAI, CHINA.

T. K. E——, age fifty-nine, farmer, was admitted to the hospital on May 24th, 1886, with an epithelioma of the penis. Has had good health, with the exception that he has constipation alternately with slight attacks of diarrhœa. Has smoked opium for nearly eighteen years, and this accounts for his bowel trouble. His parents lived to a good age. No history of any cancer trouble in his family. Rather more than three years ago he first noticed a small sore on the prepuce. This has spread until the prepuce and the greater portion of the glans have been destroyed. The disease extends down the organ towards the root of the penis. He passes his urine freely, but requests an operation to relieve the pain from which he suffers. He has a hydrocele of the left testis. There are no enlarged glands in the groin, and no evidence that the disease has involved any other parts. He is rather thin and feeble, presenting the appearance common to old opium smokers.

On consultation with my colleague, Dr. Jamieson, I proposed to make a free incision in the scrotum, dissect out the urethra and corpus spongiosum, carry my incision well down in the perineum, slit up the urethra and fasten it to the lower angle of the wound, then detach the corpora cavernosa from their attachments and remove them entirely by the use of a periosteal elevator; this operation, as reported by Mr. Pearce Gould in THE LANCET, May 20th, 1882, seeming to me the only way to remove the diseased parts in such a manner as to prevent a return of the disease. Dr. Jamieson concurred with me, only suggesting that the new urethra should be made at the operation, the parts allowed to heal, and then a second operation be performed for the removal of the penis. To this I assented. A few days were spent in trying to improve the condition of the patient. On June 7th, after the parts had been thoroughly cleansed with soap and water and a 5 per cent. solution of carbolic acid, the patient was placed under the influence of chloroform, a catheter passed into the bladder, and the corpus spongiosum dissected out just at the posterior margin of the scrotum, silk threads were passed through it, and I then divided the corpus spongiosum and dissected it well backwards. The urethra was split on its lower side, and four sutures put in to keep it in its new place at the lower end of the incision. A few vessels were tied in two places and cut between; there was some oozing of blood, which was controlled. A drainage tube was put in and the wound sewed up with a continuous catgut suture. A Gamgee pad was applied over the wound, finely picked oakum, full of tar, over this, and a bandage. The wound pursued a healthy course and healed entirely in sixteen days.

On June 26th the patient had an attack of diarrhœa after eating a quantity of unripe fruit. A few days were spent in getting over the effects of this attack. On July 6th the patient had his pubes shaved and the parts fully cleaned and disinfected. He was put under the influence of chloroform, his legs being supported by Clover's crutch. An incision was made passing round both sides of the penis along the raphé of the scrotum, and then deep down in the perineum; the penis was put on the stretch, and the suspensory ligament cut through. With a periosteal elevator the crura were peeled from their attachments, and the left testis and the hydrocele were removed. As the patient only consented to the operation on the condition that the right testis should not be removed, it was left in place. Some

but she recovered completely, and remained well until about two years ago, when she began to complain of headache, and frequently vomited, especially in the morning. For the past nine months, she has been weak in the right arm and leg, and for the last three months she has suffered almost constantly from severe headache, always localised in the forehead, above the right eye. For a month previously to her admission, it had been noticed that she was unable to move her eyes outwards, either on the left or right sides, and that the left pupil was larger than the right. For a fortnight before admission the patient had been unable to read, the letters appearing dim and blurred, and there was double vision. From the first she has had tremor in the right arm on exertion. Vertigo had been present some time, together with a staggering gait, there being a tendency to fall forwards.

On admission it was found that the grasp of the right hand was much more feeble than that of the left, and that the right leg was also weak. When she elevated her upper lip the mouth was drawn to the right side, and the left conjunctival reflex was lost. She could not close the left eye, and there was evidently peripheral facial paralysis on the left side. The tongue, when protruded, was deflected slightly towards the right side. There was no deafness or loss of taste or smell. It was found that intense neuro-retinitis was present on both sides. Nystagmus was observed when the patient looked in any direction so as to strain the ocular muscles, but there was no nystagmus when the ocular muscles were at rest. She could move her eyes freely in an upward or downward direction, but the movement outwards was much restricted on the left side, and quite lost on the right. The knee jerk was diminished on both sides, but the right was most affected. The gait was staggering, the stagger being towards the left side. The muscles of the left side of the face responded feebly to the faradic current, and with the galvanic current A.C.C. exceeded C.C.C.; on the right side of the face the electrical reactions were normal. The symptoms shortly were headache, vomiting, double optic neuritis, nystagmus, peripheral facial paralysis on the left side, slight hemiplegia on the right side, diplopia, vertigo, staggering to the left, and inability to rotate the eyeballs outwards. The diagnosis of encephalic tumour was rendered certain by the symptoms just enumerated, and the staggering gait pointed to the cerebellum as being the seat of the growth. The left facial nerve was evidently compressed by the growth, as were also the sixth nerves. A growth in the left lobe of the cerebellum by growing downwards and forwards might easily compress the left facial nerve and the sixth nerves, and by compressing the left half of the pons would cause right hemiplegia. It was thought, therefore, that there could be little doubt that the growth occupied the left lobe of the cerebellum. As to the nature of the tumour, the absence of any family history of syphilis or scrofula rendered it probable that the tumour was a glioma. While in the hospital the patient vomited several times, but otherwise her condition remained stationary. There was no fever and no albuminuria, but the urine contained earthy phosphates in excess.

After the diagnosis and prognosis had been communicated to the mother, she inquired whether any operation could be undertaken for the removal of the tumour; and though the danger, and probably fatal result, were duly impressed upon her, she preferred that her child should have the chance of its successful removal. I accordingly transferred the case to the care of my colleague, Mr. Jordan Lloyd, who supplies me with the following notes of the operation.

Operation.—The head had been shaved two days previously, washed thoroughly, and covered with lint soaked in carbolic lotion. A quarter of an hour before the operation one-sixth of a grain of morphia was injected under the skin. A curved incision convex downwards was made from the occipital protuberance almost to the base of the mastoid process on the left side. Flap with pericranium raised upwards, and muscles separated from under surface of occipital bone downwards. Two one-inch trephine discs were removed from the occiput; the pin of the trephine being applied on each occasion on a line drawn from the occipital protuberance to the tip of the mastoid process, thus ensuring the openings being below the lateral sinus. The angles of the bone between the trephine were then cut away with bone pliers, and after all bleeding had been arrested, a crucial incision was made through the dura mater throughout the length and breadth of the osseous opening. The cerebellum bulged into the wound at once, and its surface appeared darker in colour than was natural. No hardness could be felt with the finger; an incision therefore was made into the brain substance. The bleeding which followed was very free. A finger introduced into this wound recognised "softness" in all directions. Part of the cerebellar substance was cut away, and after the bleeding ceased the dura mater was stitched with catgut and the flaps with silver wire. A small drainage tube was introduced through the scalp only at the most dependent part. The wound was covered with boracic acid and dressed with glycerine, boracic, and absorbent wool. After the operation the patient was collapsed and unconscious; she became conscious twelve hours afterwards, and spoke rationally. She remained, however, in a collapsed condition, and died about forty-eight hours after the operation.

At the necropsy the cerebrum was found to be healthy. The left lobe of the cerebellum was enlarged and hollowed out in the centre, the cavity being occupied by recent blood clot. The anterior and under portion of the lobe was found bulging and pressing on the left facial nerve. On section the cavity was found to be surrounded by soft vascular tissue of a pinkish colour. The new growth had evidently occupied nearly the whole of the left lobe, and had invaded the middle lobe also. Dr. Hogben kindly cut some sections of the growth, which under the microscope showed the structure of a glioma.

In this case the new growth infiltrated the whole of the left lobe and a considerable portion of the middle lobe of the cerebellum, and its surgical removal was an impossibility. I suspected that the tumour was a large one, but had no idea that it was so extensive and infiltrated. Three cases of operation for removal of cerebellar tumour have been recorded. In THE LANCET for April 16th, 1887, Mr. Bennett May recorded the case of a boy under my care from whose cerebellum he removed a tubercular tumour, the boy dying from shock. The operation undoubtedly in this case was deferred too long, and it is probable that the boy would have recovered had the operation been performed three months earlier, for the growth was small and was easily removed without causing much damage to the cerebellum. In the *British Medical Journal* of April 23rd, 1887, Mr. Victor Horsley publishes a list of ten cases of operation upon the brain. One of these operations was for cerebellar tumour; the patient had been in bed a year, and the operation was performed as a *dernier ressort*. The patient died nineteen hours after operation from shock. There is evidently a much greater danger of death from shock in operations on the cerebellum, as we should expect from its proximity to the medulla. I consider that the only chance of success lies in the early performance of the operation—and, taking into consideration the hopeless nature of such cases when left to themselves, the operation seems justifiable.

CASES OF SPONTANEOUS RUPTURE OF THE AORTA AND HEART.

BY W. COODE ADAMS, M.B. LOND.

M. J——, a female, aged twenty-three years, of healthy parentage and family history. The patient had had typhoid eleven months before. On Monday, May 6th, she was brought home with the history that she had had an attack of pain in the cardiac region, and had become faint. She was faint on arrival, but did not complain of any particular pain. She was kept in bed for the next two days, and on the third was allowed to get up; on the fourth, being apparently well, she was allowed to go out with her sister. After walking for about twenty minutes she was seized with violent pain over the region of the heart, and immediately became faint. Her sister conveyed her quickly home, and she arrived in the same condition as on the first occasion. She was seen almost at once by her medical attendant, Dr. McMunn, who failed to detect any murmur or other cardiac physical sign. She continued faint and semi-conscious till next morning, when I was asked to meet Dr. McMunn, but she died before my arrival.

Necropsy.—On opening the thorax, the pericardium was found to be largely distended with bloody serum, and the

Digitized by Google

the left side so as to avoid the anal growth, as well as to include some of the surrounding healthy integument. The finger, with the occasional aid of a probe-pointed scissors, was sufficient to separate the bowel from its surrounding attachments, the process being attended by some hæmorrhage, three or four vessels requiring the ligature; the rest was controlled by sponge pressure. The bowel being well drawn down by a vulsellum, first one portion and then the other of the divided cancerous mass was brought within easier reach by the finger. The écraseur wire was then passed over each successively, the loop being made to include the coats of the bowel below, and the whole disease, with a good margin of apparently healthy tissue around it, was gradually detached. About two-thirds of the circumference of the bowel down to the anus were thus removed, about one-third of healthy tissue remaining. The propriety of leaving any portion of the circumference of the bowel remaining, even when apparently free from disease, has been called into question. In a recent case where an inch of the bowel anteriorly, being found free from disease, was allowed to remain, the operator afterwards expressed regret at having done so—although up to the time of the report (more than three and a half months) the patient's condition was satisfactory,—remarking that "to do excision at all, I believe it should be done completely and the whole calibre of the bowel removed, and to this course I see Volkmann assents." Notwithstanding such high authority, I cannot but think such a rule too sweeping, and that it would be more advisable to preserve as much healthy tissue as may be practicable after giving an ample margin for removal with the disease; and experience so far, although necessarily limited, appears to justify this. Where the portion of apparently healthy tissue is small, say an inch or less, the more prudent and safe course would undoubtedly be to excise the whole calibre, taking the chance of future inconveniences. No lateral incisions through the coats of the bowel, previously to the application of the écraseur, were made, these being, in fact, effected by that instrument at the same time that the disease was separated. The wound was carefully examined all round, and some small nodules of fatty tissue, which appeared somewhat harder than the rest, were cut away. The parts were sponged with a solution of chloride of zinc—an application, I believe, recommended many years ago by Mr. Campbell De Morgan, with a view to the destruction of diseased germs after removal of cancerous tumours, and sponge wrung out with Condy's lotion applied, and supported with a T bandage. No stitches to connect the mucous membrane with the integument were used, this expedient being now, for sufficient reasons, properly discarded. The effect of the ether having passed away, the patient soon recovered from the shock of the operation, and already felt the comfort of the relief afforded. My acknowledgments are due to Messrs. Eben. Davies and Fry for their kind and efficient assistance, and to Dr. Rawlings for his perfect administration of the anæsthetic. As this operation, although now justified in properly selected cases, is still to some extent upon its trial, I have thought it advisable to enter more into detail than I otherwise should have done. I have deviated in one respect from the course usually pursued and recommended. I found that when the bowel was thoroughly separated from the surrounding tissues, and the diseased mass well exposed, I could without much difficulty include within the loop of the écraseur each portion of it, together with a fair margin of healthy tissue, without making separate longitudinal incisions on each side, as already described. This had certainly the advantage of shortening the operation and (if a cutting instrument were used) diminishing the hæmorrhage, though the removal of the disease may not perhaps in this way appear so neatly accomplished as when longitudinal incisions are made, and the disease separated by a transverse section. It has, however, answered in this case exceedingly well in every respect. The sponge having been removed, carbolised oil on lint was lightly applied, and an opiate pill given at bedtime. The parts were afterwards washed with weak carbolic lotion, and Condy's fluid injections employed after suppuration was established.

With the exception of slight cystitis following retention of urine, and some hæmorrhage on the sixth and again on the ninth day—probably connected with separation of the ligatures,—the subsequent progress of the case was altogether most satisfactory. The temperature was moderate throughout, reaching its highest degree (101·9°) on Nov. 20th, becoming normal on the 27th, and rising to between 99° and 100° for a few days afterwards. From Dec. 8th to 11th, there was a little rise associated with a slight erysipelatous blush around the wound, which, however, soon subsided. Some hard fæcal lumps were passed on Nov. 26th, and after a mild aperient good relief was obtained on the 31st. The bowels acted with fair regularity after that time, a little assistance, mechanical and medicinal, being sometimes required. There was an occasional involuntary discharge of a small quantity of liquid fæces, but after a short time this inconvenience ceased, and the control over the bowel became complete, and has continued so ever since. On Dec. 18th, the patient sat up, came down stairs on the 25th, and took walking exercise on Jan. 1st. Since that period her progress in all respects has been uniformly favourable, the bowels acting regularly and without the least inconvenience, the control, as I have said, continuing perfect. She describes herself as feeling better than she has done for some years; the sense of uneasiness and distress experienced during that period and the acute suffering for several months before the operation having entirely ceased.

On May 30th—that is, six months and a half after the operation—I made a careful examination of the patient. Upon a superficial inspection the only indication of any operation is a smooth, scarcely perceptible cicatrix. A short distance above the natural situation of the anus is a circular aperture, formed by slightly yielding cicatricial tissue, just large enough to allow by gentle pressure the passage of the fore-finger, which was grasped apparently by a slight sphincter action. There was not the least sensation of morbid induration or growth in any part, and the bowel above felt throughout soft and perfectly healthy. The patient's general health and strength keep exceedingly good, and, as I have already mentioned, she suffers no inconvenience whatever. To estimate the value of the operation, even at this period of time, we have only to compare her present condition and prospects with what they would inevitably have been if the disease had been allowed to take its course. To refer further to the contrast is needless.

The following quotations are sufficiently representative of the views held with regard to this treatment a few years ago by our most eminent surgeons: "The treatment to be adopted for malignant disease of the rectum can offer no other service, unfortunately, than that of palliating the disease, assuaging pain, and prolonging the duration of life." "Some surgeons were, a few years since, in the habit of performing excision of the lower part of the rectum when affected with cancer; but this proceeding must be looked upon as both barbarous and unscientific, and it is now, happily, exploded from the catalogue of surgical operations." (Holmes' System, 1st ed.) In place of the last paragraph, it is stated in the last (3rd) edition, 1883, that the operation is "one surrounded with so much danger and difficulty that it is only in rare instances, when the disease is limited to the lower two inches of the bowel, that the surgeon is justified in performing it." "The recommendation to excise the cancerous mass, as made by Lisfranc and other French surgeons, is contrary to every principle of good surgery; as it is impossible to extirpate the whole of the disease, without either laying open the peritoneal cavity or destroying the patient by the profuse hæmorrhage, which could scarcely be arrested." (Erichsen, 6th ed., 1872.) In the last edition, 1884, however, the operation is spoken of as one "that in well-selected cases, and taken early, holds out a fair prospect of prolonged relief or even cure." "Palliative measures are alone practicable. That such a procedure [excision of the cancerous mass] is justifiable may well be doubted." (Gant, 2nd ed., 1878.) And so on with other recognised authorities.

CASE OF CEREBELLAR TUMOUR; OPERATION; DEATH FROM SHOCK.

By C. W. SUCKLING, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

E. C——, a girl, aged twelve, was admitted into the Queen's Hospital on March 28th of this year complaining of headache and dimness of vision. The family history was a neurotic one, one of the mother's brothers having had fits, and the father's uncle and father having had "strokes." There was no family history of phthisis or struma. The patient suffered from scarlet fever when three years of age,

Digitized by Google

orbital arch was much depressed, but not perforated by the tumour as I had anticipated. Having stopped the bleeding completely, I now united the wound by first intention, leaving in the cavity occupied by the tumour a drainage tube, which descended to the left nasal fossa through the opening made on the ethmoid by a prolongation of the neoplasm; then I closed the nasal cavity with an iodoform tampon. The operation lasted about an hour. The patient bore the chloroform very well, showing only the weakness following the use of an anæsthetic and attendant upon loss of blood. On the third day she had fairly recovered, and the wound was healing without suppuration. The drainage worked well, a large quantity of serum tinged with blood flowing through it. On the fourth day, however, the patient was overtaken by sudden prostration, was inclined to sleep, exceedingly disinclined to talk, and complained of mental confusion. I then discovered that the drain had stopped during the night, so I at once removed the tampon, replacing it, however, further down the nasal cavity. The effect was good; the serous fluid began to drip again. Not satisfied with this, I applied a gum-elastic "pump" to the external opening, and drew off about thirty grammes of liquid. The flow was thus re-established, and continued all the following day and night. On the renewal of the flow the alarming symptoms disappeared as if by magic. On the seventh day I removed the stitches and the drainage tube, and on the fifteenth day the patient returned to her home, doing very well. She had lost that sensation of vacuity around her person which made her uncertain in her movements, but had not regained her memory or the sense of smell.

Three months after I presented my patient to the Chirurgical Society at its meeting in Perugia in 1884. She was in a happy frame of mind, and willingly related her experience. She stated that now all her faculties and moral conditions were normal, and that she had even regained her sense of smell. This greatly surprised me, for I felt sure that I had destroyed the left olfactory in removing the tumour, which had destroyed the cribriform lamina of the ethmoid. Upon experimenting, however, with aromatic substances, we found that she could only smell with the right, and that the left was totally insensible, its olfactory having been destroyed either by the pressure of the tumour or by the operation itself. The part of the bone which had been removed was now partially reproduced, the cavity in the region of the operation had disappeared, and the eye had regained almost entirely its normal position. The tumour, under the microscope, presented a multiform fibrocellular structure of sarcoma.

It is now four years since that operation was performed, and my patient is in perfect health. My diagnosis and the operation, apparently so hazardous at the time, are therefore justified by the result. And, though such operations have generally failed, the success of mine should secure proper consideration at the hand of modern surgery.

The progress of experimental pathology and of studies of cerebral localisation every day now smooths our way to the diagnosis of cerebral diseases, so that the cranial cavity may in future justly enter into the dominion of surgery. The frontal and parietal regions can now be successfully attacked by the scalpel of the surgeon, and many affections of the meninges become trophies of rational surgery.

Rome.

CANCER OF THE RECTUM; EXCISION; RECOVERY.

BY GEORGE PADLEY, L.R.C.P. LOND., &c.,
CONSULTING PHYSICIAN TO THE SWANSEA HOSPITAL.

IN relation to an operation so strongly and universally condemned as that of removal of cancerous disease of the rectum by excision has been by our highest surgical authorities until a few years since, and only quite recently recognised as an admissible procedure, every addition—especially, perhaps, on the side of success—becomes important as a contribution to the statistics bearing upon the subject. With this view I send the following case, in which up to this time—more than ten months after the operation—the success has been perfect in all respects.

In the middle of August, 1886, I attended Mrs. W—— in her confinement. She was forty-seven years of age, had one child six years previously, and had not been again pregnant until the present occasion. She complained during the later period of her pregnancy of piles and of a soft swelling, which proved to be a large mass of varicose veins in the right labium. Gentle laxatives and an abdominal belt gave some relief to these, as well as to the bearing-down pressure of which she also complained. The labour, which occurred at full time, passed off satisfactorily, a large child was born, and she made a good recovery. Early in October I was asked to prescribe for "piles," of which she again complained. Some relief was afforded by treatment, but towards the end of the month her husband called to tell me that the so-called piles were again very bad, and that she had suffered very acutely during and after defecation, with occasional slight puriform discharge. From his description I inferred that she must be suffering from some ulceration of the rectum, and I arranged to visit her for the purpose of an examination. On making this I found a tumour like a pile about the size of a small filbert projecting from the anus towards its left side. On further exposing this, there appeared a jagged malignant-looking ulceration running down its centre. On passing my finger into the rectum, I discovered, extending upwards from the protrusion at the anus, and about an inch from its margin, a hard cancerous mass, with a central jagged ulceration, having raised, indurated, and everted edges, continuous with that at the anus, and extending nearly its whole length. The size of this tumour, which projected considerably into the calibre of the bowel, was about three by two and a half inches; it occupied about one-half the circumference of the bowel and somewhat to the left side posteriorly. I could just get the point of my finger fairly above its upper margin, beyond which, and surrounding the mass, the mucous membrane and subjacent structures appeared to be free from disease, excepting where it extended from its lower margin and became continuous with that portion which projected from the anus—the mass itself being freely movable over the tissues surrounding and external to the bowel. The patient had complained for years of undefinable uneasiness in the lower part of the back, with occasional passing of a little blood, but without pain in defecation. This became more marked during the earlier months of pregnancy, though not especially complained of, and continued up to the period of parturition. Since that period the symptoms became aggravated, with tenesmus and the other symptoms before referred to, which were attributed to piles. She appeared in other respects in good health; stout, but somewhat flabby in texture; of a highly nervous temperament, though otherwise strong; and her constitution presented no indication of being affected by the malady. The sacral and coccygeal glands were unaffected. There was a small, not hard, inguinal nodule in the right groin, which appeared to be quite unconnected with the rectal disease, and to be innocent in character, the glandular system elsewhere being free. Her family history was also exceedingly good. It therefore appeared to me a promising case for excision, and I communicated my opinion to the patient's husband and friends, who, with herself, left the matter entirely in my hands. Before, however, finally deciding upon it, I expressed a desire to have a consultation, and Mr. Ebenezer Davies kindly saw the case with me, and concurred in my opinion. During the period I have referred to, I may mention that the pain was much mitigated and her general condition improved by gentle laxatives and tonics, and by iodoform applied to the ulcer at and a little above the anus.

The operation was performed on Nov. 18th. The bowels having been well cleared, ether administered, and the patient secured in the lithotomy position, the left forefinger was introduced into the rectum, its tip reaching above the diseased mass, and brought into contact with the point of the coccyx. A curved sharp-pointed bistoury was then carefully guided by the finger to this point, thrust through the coats of the bowel, and made to emerge through the integuments in the middle line behind the anus. The intermediate tissues, including the diseased mass itself, were then cut through by one sweep of the knife (Denonvilliers' incision)—a preliminary step in the operation which has so largely contributed to its practicability and success, though its importance has not yet received on all hands adequate recognition. The nates being well separated, two curved incisions were then made, one on either side of the anus, together including about two-thirds the circumference of the bowel, the knife being carried well into the ischio-rectal space. The curve was made wider on

ease, cleanliness, and safety of administration more than compensate for their slightly retarded action. They are specially valuable in the treatment of those phenomenal children who have an invincible repugnance for medicine in any form, and who manage to spit it out or vomit it up, notwithstanding all sorts of threats and caresses. Medicated suppositories will in these cases relieve the parents as well as the patient, and make the doctor's life more bearable. The main indication for rectal medication in cutaneous as well as other diseases is inability of the stomach to receive or retain the medicine needed to restore health. As this is the only criterion, it is obvious that it would be impossible to enumerate the affections of the skin in which rectal medication would be valuable and those in which it would be useless. Every case must be judged in accordance with its own requirements.

If the symptoms present are such as are usually antagonised or removed by the systematic action of a certain drug, and the gastric mucous membrane is so disordered that that drug is immediately rejected by vomiting, our duty is to endeavour to procure its absorption in another manner, rather than to discard it and search for another remedy.

In many cases of syphiloderma mercury will not be tolerated by the stomach, and the patient's habits or business affairs are such that inunctions, hypodermatic injections, or fumigations cannot be employed. In these cases I have repeatedly witnessed the disappearance of the eruption and the recovery of the patient from the employment twice a day of suppositories containing half a grain of calomel or a quarter of a grain of the protiodide of mercury. Infantile syphilis may be effectually treated in the same way, reducing the quantity of calomel to one-twelfth of a grain, and the protiodide to the one-twentieth or the one-hundredth part of a grain. The bichloride or any of the other preparations of mercury may be substituted in appropriate doses.

Scrofuloderma is almost invariably benefited by cod-liver oil, but patients are occasionally met with who are unable to take it in any form. In two mild cases of this disease under my care recently, in which this idiosyncrasy was extreme, I effected complete cures by the employment of rectal enemata of one ounce of cod-liver oil every night, continued for five weeks in one case and in the other for two months.

Erythema multiforme and erythema nodosum, when due to malaria, are usually accompanied by so much gastric irritability that even water is vomited as soon as it reaches the stomach. Twenty grains of quinine, made into a suppository and inserted in the rectum, will relieve all the symptoms in a few hours.

Urticaria nodosum, a somewhat similar affection, will promptly yield to the same treatment. Urticaria simplex, due to the presence of fermentative or irritating material in the gastro-intestinal canal, can be more speedily relieved by the rectal injection of an ounce of castor oil and an ounce of glycerine than by any other method.

Erythema intertrigo, when produced by the irritation of diarrhœal discharges, can frequently be removed almost immediately by the use of a single suppository containing a small quantity of opium combined with from five to twenty grains of a vegetable astringent like geranium or hamamelis.

Pruritus ani is often due to an œdematous condition of the tissues around the anus. In this event antipruritic lotions and ointments can be of only temporary utility, and occasionally aggravate, instead of alleviating, the patient's sufferings. A suppository containing ten grains of powdered geranium or ten grains of quercus alba will dissipate the œdema and banish the itching. Pruritus vulvæ and general pruritus are occasionally traceable to disorder of the anal nerves, and can then be almost magically relieved by the employment of suppositories composed of half a grain of opium and half a grain of extract of belladonna, or half a grain of opium and five grains of chloral; ten grains of quinine and half a grain of extract of cannabis indica is also useful. Arsenic and antimony are of incalculable benefit in many cases of psoriasis, but they frequently disorder the stomach so much that their administration is suspended before the eruption is removed, and some less potent but less irritating remedies substituted. My experience has convinced me that to discontinue their use under such circumstances is an error. They can be given with advantage in the form of suppositories. Care must be taken, however, to have them evenly divided throughout the mass, and to employ at least one-twentieth of a grain of arsenious acid or arsenite of sodium in each suppository, one to be used from one to five times a day.

Iodide of potassium is of great service in many cases of subacute and chronic eczema, but its peculiar recurrent taste and the additional eruption which is occasionally developed by it limit its employment; if it be given in small doses in the form of suppositories these unpleasant drawbacks will be rarely observed. There are some cases of obstinate eczema in which rectal enemata of cod-liver oil will be more successful than any other remedy. Ichthyosis may be signally palliated by the same method. Many other cutaneous affections might be mentioned in which rectal medication will prove valuable, but I prefer to limit my remarks to those in which I have realised its value by practical experience.

Philadelphia.

CONTRIBUTION TO ENDOCRANIAL SURGERY.[1]

BY F. DURANTE,
PROFESSOR OF SURGERY.

IN May, 1884, C. B——, a woman, thirty-five years of age and a native of Narni, came under my care. Her general appearance was good; she seemed well nourished, although not of a very robust constitution. Externally, she showed no abnormality, except as to her left eye, which appeared somewhat low and drawn outwardly, otherwise the movement as well as the functions of the globe were normal. This deformity had manifested itself only within the three months previous to her visit to me. For a year or more however, she had entirely lost her sense of smell, her memory had become impaired, particularly as to remembering names, and she experienced a peculiar sensation of vacuity which caused her to feel uncertain in her movements. Motion, sense of touch, and sensibility to heat and pain remained natural. From her husband I learnt that she had somewhat changed in disposition; that from being generally happy and bright, she had become sad, melancholic, and taciturn, although she did not seem to brood over the state of her health. The senses of hearing and taste, and the functions of the chylopoietic viscera were perfect; also nothing abnormal was found on a close examination of the nasal and pharyngeal regions. The course of the disease, the loss of memory and of the sense of smell, and the objective and subjective state of the patient led me to believe in the presence of a tumour within the cranium, the pressure of which affected the anterior lobe of the brain and paralysed or destroyed the olfactory nerve. Moreover, the displacement of the globe of the eye led me to believe also that the tumour had penetrated the superior arch of the orbital cavity. Such being my diagnosis, I now proposed to the patient an operation that would remove the offending object, explaining to her the gravity of the operation without reserve. She was brave, and she consented.

To reach the tumour it was necessary to make a large opening in the left frontal bone; so with an incision commencing from the inner angle of the left orbit upwards nearly to the hair line as far as the temporal region, I raised all the soft tissue from the bone in a flap. The bone being exposed, with a sharp scalpel and hammer I removed a large portion of it, commencing at the superior orbital margin, inferiorly, and found that the internal parietes of the frontal sinus had been forced outwardly. The dura mater being now exposed, I examined it, and found that it had been perforated by the tumour just opposite the frontal eminence. With great care I now began to scoop out the tumour. As soon as a considerable portion of the tumour was removed, I detected that it did not adhere beyond the internal surface of the dura mater, and that therefore its enucleation was comparatively easy; and then removed it and carried with it all the adherent portions of the dura mater. The hæmorrhage was slight and easily controlled by the hæmostatic, a tampon treated with sublimate. The tumour was lobular, of the size of an apple, and weighed seventy grammes. It occupied the anterior fossa at the base of the left cranium, extending to the right and upon the cribriform lamina, which it destroyed. Posteriorly it extended to the glenoid tubercles before the sella turcica. The left anterior cerebral lobe was greatly atrophied; the

together with much fibroid growth, into a funnel, of which the axis would give passage only to the point of the little finger. The curtains, or what represented them, were stiffened, though not to absolute rigidity; they could be made to close perfectly; it appeared that they must have done so towards the end of ventricular contraction, but that their closure must have been delayed by their stiffness was equally evident. The tricuspid valve was thickened after the manner of the mitral, but not to the same extent. The aortic valves were slightly thickened, and on them were a few minute vegetations; there appeared to be nothing which could interfere with their action. The pulmonary valves were natural. The left ventricle was dilated and thin, the right dilated and thickened. The left auricle was greatly thickened, not greatly dilated.

Some cases which illustrate the point in question together with another are to be found later on. So far, I think, I have shown that there are reasons to believe that the so-called presystolic murmur is systolic and regurgitant; that though correctly regarded as a sign of a contracted mitral valve, it is equally a sign that the valve so altered has not lost the power of closure.

The court of the last appeal is pathological. The question to be asked—one to which the experience of the future, if not of the past, will return a conclusive reply—is this: Is the so-called presystolic murmur, with its concluding snap, or what sounds like one, ever made by a mitral valve which cannot close either in whole or part with the closing ventricle? Can this murmur exist with an absolutely rigid, permanently patent, orifice? I have seen no instance, but my experience is not infinite. If this can be shown to be possible, then much that I have said requires modification.

I may add a word about the "presystolic murmur" which, in orthodox phraseology, "runs into the systolic." Though the terminal snap is the chief characteristic of the murmur in question, yet its intensity, its rumbling tune, and its earliness in the systole are also characteristic. Thus the murmur may possibly be recognised, though the snap be wanting or be only imperfectly developed. If the view I am advocating be correct, this must happen whenever the mitral orifice is so contracted as to give to the regurgitant murmur the special characters which belong to the so-called presystolic, while the valve is incapable of closing, or closes only incompletely, so that the murmur goes on unstopped to the end of the systole. In this case we should have an early murmur of the "presystolic" character continued into a late one, possibly not distinguishable from the common mitral regurgitant, both actually systolic and regurgitant, not strictly two murmurs but one, though the beginning might be a little different from the end. I have shown, or tried to show, it to be impossible that a true presystolic or mitral direct murmur should "run into" or be continuous with a mitral regurgitant; how, then, are we to explain the fusion, when "the presystolic runs into the systolic," but on the supposition that both are regurgitant, or rather that there is but one which begins early and ends late—"linked sweetness long drawn out"?

(To be concluded.)

RECTAL ALIMENTATION AND MEDICATION IN DISEASES OF THE SKIN.[1]

By J. V. SHOEMAKER, A.M., M.D.

THE power of the rectal mucous membrane to absorb substances placed in contact with it is but little inferior to that of any other portion of the gastro-intestinal canal. Moderate quantities of milk, eggs, gruel, blood, beef-tea, and all the nutritious broths are absorbed by the rectum almost as quickly as by the stomach. Ether and other volatile agents produce their characteristic effects immediately after their introduction into the rectum. Solutions of morphia, atropia, aconitia, quinia, and hyoscyamina are taken up as rapidly, and strychnina and nicotine more rapidly, by it than by the stomach.

As a general rule all substances in solution are speedily absorbed by the rectum, unless they are so irritative in character as to produce muscular contraction, which will only cease upon their expulsion. Solids, [illegible] substances in powder or in the form of [illegible] taken up more slowly, but eventually [illegible] administered in the usual manner, [illegible] with the fæces before absorption is complete. The absorbent properties of the rectum are frequently availed of in the treatment of gastric irritability, ulcer of the stomach, and carcinoma of various portions of the alimentary tract. By giving the stomach absolute rest, and nourishing and medicating the patient by the rectum, the duration of acute attacks is lessened, life in many cases saved, and in others prolonged for months. The same methods which yield such gratifying results in these diseases may also be employed with decided benefit in many cutaneous affections.

In epithelioma of the lips and tongue, after excision has been performed, patients are usually fed through a rubber tube; but notwithstanding the greatest care on the part of the patient and nurse, the movement of the muscles in swallowing conveys more or less irritation to the edges of the wound, and may in some cases stimulate the morbid process to renewed activity. It would be much better in such cases to place the oral muscles at complete rest and nourish the patient by the rectum until the wound is completely healed. The same method should be adopted for several days after cauterising or scraping lupus spots on the lips or in the mouth.

In stubborn cases of infantile eczema, in which the little patient, while retaining all the food it takes, and presenting no symptoms of gastro-intestinal disorder, yet does not increase in weight, immediate improvement will often follow the administration of one ounce of milk by enema four times a day. In these cases, which may be termed examples of infantile apepsia, the skin affection is clearly the result of insufficient nutrition.

Obstinate cases of pemphigus and impetigo in children of all ages are frequently due to the same cause, and are promptly relieved as soon as supplementary rectal nutrition compensates for deficient gastric assimilation.

There is an intractable form of recurrent acne observed in young girls and delicate boys, which on inquiry will be found to be closely associated with stomachic debility. When their appetite is good and digestion perfect the eruption disappears; but after a time, without apparent cause, their appetite lessens, the sight or smell of food produces a feeling of nausea, and if they force themselves to eat as much as formerly, they vomit it soon afterwards. They become pallid and weak, and the eruption, usually consisting of from one to a dozen papules, reappears. Investigation fails to disclose the portion of the digestive system at fault. The tongue remains clean, the bowels are normal, and all the bodily functions, except those eating and assimilating, are performed as usual. The routine treatment for these patients consists of iron, strychnine, the mineral acids, and the various bitter tonics, and it usually terminates in success in from two to six months. Many of them could be cured in from two to four weeks by combining the rectal administration of milk, malt extract, and beef juice with the internal medication previously referred to.

A general rule which may be safely followed in the treatment of all diseases, whether of the skin or any other organ or portion of the body, is: Whenever the system manifests evidence of insufficient nutrition, supplement stomachic assimilation by the administration of nutritious enemata. The only exception to this rule is when the rectum is unable, either from irritability or disease, to retain the enema long enough for absorption to occur. Care should be taken in the preparation of nutritious enemata to ensure their retention. If too large, they will overdistend the rectum and produce vigorous contractions, ending in expulsion. If too cold or too hot, the same result will also occur. They should be lukewarm, and not exceed four ounces for an adult and one ounce and a half for a child. They ought not to be given oftener than once every four hours, or they may induce an irritable condition of the mucous membrane. The advice of some authors to empty the rectum of fæcal matter by an ordinary injection before giving an enema intended for absorption is ludicrous. Every surgeon knows that the rectum, as was pointed out by O'Byrne forty years ago, is normally an empty pouch until defecation begins.

RECTAL MEDICATION.

In cutaneous diseases suppositories are the most convenient form of medicating the system by the rectum. They are absorbed more slowly than solutions, but their

I have not received much help from the cardiograph, in the use of which, however, I must confess want of skill. I have found myself better able by simpler means to time the impulse and determine its relation to murmurs. As an improvement, or rather a refinement, on the pin and cork, I had made, with Mr. Hawksley's help, a simple long light lever, one end of which is in relation to a wedge in the intercostal space, while the other is free to oscillate with a magnified movement; but I will not describe this apparatus in detail, as I have not found any constant advantage with it as compared with the pin and cork. The more complicated machine is less ready to respond to a very weak impulse, though with a fair impulse it gives a longer movement. I need not say more about it than that the indications it gives correspond with those obtained by other methods, and show that the murmur and the movement of the ventricle begin at the same time.

On this showing the murmur is systolic, and it may be added that the thrill which sometimes accompanies the murmur is so too. A systolic mitral murmur is regurgitant; this, therefore, is the character of the murmur in question. But it has certain peculiarities. The ordinary or old-fashioned mitral regurgitant murmur simply takes the place of the whole first sound, and lasts to its end. The murmur which is in question replaces the early part of the first sound, and then finishes with a snap (to use Dr. Ormerod's phrase), which, though it does not much resemble a normal first sound, represents it, since it stands in its place. We now approach what I take to be the key of the position: Why is the first sound, thus altered, shortened and sharpened into a snap? Why does this altered first sound follow the murmur, while the ventricular contraction, as I have shown, accompanies it? The view I submit, as one founded on the careful putting together of clinical and post-mortem observation is this: The mitral orifice in these cases is always constricted, but the valve nevertheless allows of regurgitation during the first part of the systole, while it is able to close as the systole proceeds, so as to stop regurgitation towards the end of that movement. The mitral valve is often converted into a mere stiff funnel of fibrous tissue with a button-hole at the bottom. The stiff and slow-moving curtains—if curtains they can still be called—necessarily allow of regurgitation for a time, but with the advancing contraction of the ventricle they come together, late rather than never, and with their closure make the short sharp sound which replaces the normal systolic sound and gives the distinguishing note to this ill-omened harmony.

The essential factors of the so-called presystolic murmur are therefore mitral regurgitation, succeeded by mitral closure. The regurgitation begins where the ventricle is at its widest, the chordæ tendineæ at their furthest stretch, and the valve in its most open phase. If regurgitation ever takes place, it must be now. But the regurgitation terminates, and that abruptly. As the ventricle narrows, the chordæ tendineæ slacken, the blood continues to press on the ventricular aspect of the valve, the transformed flaps, rigid as they are, get together, the murmur is at an end, and the modified systolic sound is produced. The delay in the closure of the valve shows it to be abnormally stiff; the fact of its closure, notwithstanding the stiffness, is an indication that the orifice is small enough to be closed with the reduced amount of movement which the stiffened valve can accomplish. Thus this sequence of murmur and sound is diagnostic of mitral constriction, though the murmur is actually not one of obstruction, but regurgitation. In support of the view I have presented I might adduce much pathological evidence, to the effect that when the so-called presystolic murmur has been heard during life, after death it has been found, first, that the mitral orifice was contracted, and, secondly, that the valve was capable of closure. To this statement I have come across no exception. I may relate in brief, from my experience at St. George's Hospital, a few instances, to which it would be easy to add, in support of the proposition I have advanced.

Charles W——, aged thirty-nine, died while under my care on May 22nd, 1886, of heart disease. In the absence of my own notes, I quote from those of the medical registrar. "A presystolic murmur of short duration was heard over the apex with a duplicated second sound." With regard to the post-mortem condition of the heart I found on my own observation. The mitral flaps were greatly thickened with fibroid material; they were not shortened, but were adherent to each other at their sides, so as to convert the valve into a tube or funnel, of which the lower opening was of about the size of the button-hole of a coat, and would just admit the little finger. On the inner aspect of this tube at its auricular end was a good deal of rough atheroma, but towards the ventricle it was fairly flexible, and with a little lateral pressure closed with apparent completeness.

Sarah C——, aged sixty-eight, admitted on Oct. 6th, 1886. Heart irregular. At apex short, rather intense murmur, which would commonly be called presystolic. The first sound was abbreviated and sharpened. The murmur was placed in the first part of the systole, as estimated by the impulse, the altered first sound occupying its latter part and forming its conclusion. A double aortic murmur had been noted by the medical registrar in addition to the mitral, but was not heard by me at the time the preceding note was taken. My purpose is only with the mitral murmur, which was characteristically of the "presystolic" kind. Shortly after these observations were made the patient died. The curtains of the mitral valve were excessively thickened with fibroid structure, in which were embedded nodules of a bony consistence. The orifice was narrowed so as to admit only the end of the thumb. The valve flaps could be brought together, though with difficulty. It was apparent that regurgitation must have taken place in the early part of the systole, while at the later part it was probably arrested. There must also have been auriculo-ventricular obstruction, though not to an extreme extent. The aortic cusps were thickened and contained calcareous matter; they were apparently incompetent.

Thomas R——, aged twenty-six, was admitted under my care with heart disease on Oct. 11th, 1886, and died on the 23rd. There was a loud so-called presystolic murmur at the apex, now without thrill, though a thrill had been perceptible on a previous admission two months before. The murmur was long, intense, and very characteristic of its kind. It was immediately succeeded by a sharp short sound not unlike the second sound, but actually a modification of the first; this was followed by a normal second sound. The heart's sound was at times very rapid and irregular, two or more beats corresponding to one of the pulse. On one occasion 136 beats of the heart and 56 of the pulse were counted in the same minute. The mitral orifice was much contracted, and the valve transformed by old fibroid thickening. The narrowing was not so extreme as is sometimes seen, the aperture admitting the ends of two fingers and measuring about one inch by half an inch. The inside of this channel was comparatively smooth, so that there was no great suggestion of an auriculo-ventricular murmur. It was obvious that regurgitation must have taken place during the systole of the ventricles, and possible that towards the end of the systole the valve may have closed.

Emma W——, aged thirty-seven, was admitted on Jan. 30th, 1887. She had had rheumatic fever three times; first when eleven years old. She had hæmoptysis a month before admission. When taken in, her general symptoms were those of mitral disease with broncho-pneumonia, from which she died on Feb. 22nd. In the early part of her case there was a suspicion of an apex murmur, which by Feb. 16th had developed into a well-marked so-called presystolic. The heart was rapid, and though there was a hint of a diastolic murmur as well, this could not be recognised with certainty. After death the mitral flaps were found to be enormously thickened with fibroid tissue, and united laterally, so that they converted the valve into a funnel, the opening at the bottom of which was a mere slit like a button-hole, about large enough to admit a cedar pencil. A little lateral pressure with the finger sufficed to close this aperture, so that it did not seem possible to doubt that, though the closure of the valve must have been delayed by its stiffness, it was accomplished with the advancing contraction of the ventricle. The aortic valves were slightly thickened, but seemed fairly efficient. The tricuspid and pulmonary valves were practically natural. The left ventricle was small, the right much hypertrophied. There was a little recent lymph in the pericardium.

Charlotte T——, aged twenty-four, was admitted on March 25th, 1887, with recent hemiplegia, the result, as was thought, of embolism. A well-marked so-called presystolic murmur was always audible at the apex. There was now no thrill, but it was said that there had been one at an earlier date when the woman was an out-patient. The cerebral symptoms became aggravated, and she died on April 3rd. The mitral valve, of which the flaps were adherent to each other at the sides, was transformed by this

Digitized by Google

Dr. Ormerod was a "product of the theoretical imagination." He asked Dr. Ormerod whether he could be quite certain that he had ever heard such a murmur, a certainty which had not presented itself to Dr. Gairdner during at least a dozen years, in which he "had been accustomed to recognise the auricular systolic murmur as that of mitral obstruction." That mitral obstruction was to be recognised by the murmur thus described became apparent to everyone, and Dr. Gairdner's position became that of orthodox medicine; but there are minds to which orthodoxy is not binding—to some it is even distasteful—and in the year 1872 the late Dr. Barclay[5] of St. George's Hospital published a critical examination of the received view, which appears to me to be conclusive, perhaps because his opinions almost exactly correspond with my own. Dr. Barclay maintained that the so-called presystolic murmur was really systolic, and that, though indicative of a contracted mitral orifice, it was regurgitant. He believed the murmur to occur at the beginning of the systolic contraction of the ventricle, which was naturally soundless. He drew attention to the absence of valves in connexion with the pulmonary veins, pointed out that with no means of closing the outlet backwards the auricle could exert but little power in driving the blood forwards, and maintained that it was "scarcely possible that one of the loudest and roughest murmurs ever heard in cardiac disease should be produced by the contraction of the auricle." The murmur was produced, in his view, by the action of the ventricle driving the blood backwards through a contracted and thickened valve, the closure of which was delayed by its rigidity, but which nevertheless shut at last, stopping the murmur with the sharp click which resulted from the shutting, and representing the first sound.

Against Dr. Barclay Dr. Balfour[6] argued that, though the veins which feed the auricle have no valves, the valves in the pulmonary artery, nevertheless, suffice to stay the backward current and allow the whole force of the auricle to be exerted forwards. But between the auricle and the pulmonary valves lie all the channels of the pulmonary circulation, furnishing, not a rigid cavity to be compared, as Dr. Balfour compares it, to a Bramah press, but a very elastic and distensible one, the blood within which must form at best but a yielding backstand. Dr. Balfour further argues that the pulmonary veins, as they approach the auricle, are capable of closure by the increasing strength of their own circular fibres, and as they enter it by the arrangement of the auricular fibres about their mouths. But allowing fully for these hindrances to the backward course of the blood from the auricle, they cannot convert this thin-walled chamber into a ventricle, or, as it appears to me, give to an auricular systolic murmur such force and intensity as belong to the murmur known as presystolic.

I believe Dr. Barclay to have been correct in the views I have quoted. I have indeed myself arrived independently at the same conclusions; but they were not generally received; and when after his death his labours were reviewed, according to custom, by the President of the Medical and Chirurgical Society,[7] this contention of Dr. Barclay's was rewarded by the negative praise of doing him credit by the courage it displayed, and was made use of to point a moral concerning intellectual cowardice—a fault from which Dr. Barclay was held to be exempt.

The articles of belief which I propose to take into question are these: The murmur is produced by the passage of the blood from the auricle to the ventricle; it belongs to the auricular not the ventricular systole, which latter it precedes but does not accompany. I shall attempt to show, on the other hand, that the murmur belongs to the systole of the ventricle; that it is systolic, not presystolic; and that it is due to mitral regurgitation, though this process is modified in a way which was foreshadowed by Dr. Barclay, and which I shall hope to make more clear. At the outset it must strike everyone as surprising that this murmur, so loud, intense, and definite, should be produced, or mainly produced, by so feeble a cause as the contraction of the auricle. It is true that the auricular contraction may be assisted in moving the blood by the expansile or suction action of the ventricle, but this also must be a feeble force compared with the contractile power of this muscular chamber. The tone and character of the murmur, therefore, are more suggestive of an origin in ventricular than in auricular contraction.

Next, this so-called presystolic murmur is described as "running up to the systole," as being united to the systolic sound without separation, and as being inseparately blended with the systolic murmur, should there be one. Let us see now what this implies in the case of this double mitral murmur. The two have become one. The presystolic and the systolic are so joined together that no man can put them asunder, or say where one begins and the other ends. But the two are distinct in their nature, though made at or about the same place. They are made by the blood going different ways to and fro through the mitral orifice. Is it possible that this should be so, and yet no halt or break of rhythm be perceptible? I should as soon expect the upstroke and the downstroke of a steam engine to blend together into a continuous harmony. Is there not always an interruption distinguishable to the ear between inspiration and expiration? Let a person blow into a tube, and then draw the air back; he cannot do it so quickly but that an interruption in the sound marks the change of direction. To come nearer to the point; when there are two murmurs at the aortic valve, systolic and diastolic, though one may follow the other as quickly as a change in the direction of the blood can be accomplished, can we not detect an interval, or at least a lack of continuity, between them? Hence I maintain that if there be double mitral disease, obstructive and regurgitant, the murmurs which arise must be separable; however close, they cannot be continuous; yet this they must be if the present theory of the presystolic murmur be right.

It is necessary to insist upon the meaning of the word *systole* and the essential distinction between systolic movement and systolic sound. The word *systole* means contraction, not noise. The contraction produces the noise. If, as we commonly believe, the cause precedes the effect, the contraction must come first. But, apart from the mere logical distinction, which may be too fine to grasp, it may be that the sound is not developed until a tangible interval has elapsed from the beginning of the contraction—until it has done something, whatever that may be, which is the immediate cause of the sound. I shall try to show that this is so in these cases. If anyone is contented to call the murmur in question presystolic because it precedes the systolic *sound*, I have nothing to say against his belief; but if it is to be so called as implying that it precedes the systolic *action*, then I am at issue with him. I have satisfied myself and confirmed my conclusion upon many patients that the so-called presystolic murmur does not precede the impulse of the heart, but begins with it; in strictness, it is systolic, not presystolic. It requires practice and opportunity to make sure of this observation, but I have convinced myself of its correctness. It is less easy to make two senses work together in exact consent than to make successive observations with one. It is easier to say that one sound succeeds another sound than to be sure of the exact time of a sound with regard to a tactile or visual impression. Thus it is not so easy as it might at first appear to place in their exact relations the impulse and the sounds of the heart. If touch is to be our guide, the best plan is to place the fingers and the end of the stethoscope as close together as may be, where both the murmur and the impulse can be appreciated. I need not insist that the radial pulse, and to a less extent the carotid pulse, are misleading as indications of the beginning of the ventricular contraction, since they both occur after it. The fingers upon the apex pressed in between the ribs supply the best tactile sign of the commencement of the systole; while a guide, which is sometimes more decisive, may be found in the movement of pins as presented to the eye. This is no novelty in cardiac diagnosis. A piece of cork should be cut so that its lower part presents a blunt wedge, which may be pressed into the intercostal space over the apex, while the top left flat is held down with crossed strips of diachylon plaster tightly stuck to the adjacent skin. Through the plaster into the cork is inserted a long pin—a light shawl pin, with a conspicuous but not heavy head, serves. If the things are successfully fixed, the movement of the ventricle will be made apparent by that of the pin, a short oscillation of which will begin with the systolic impulse. If now the observer will place his double stethoscope where the so-called presystolic murmur can be distinguished, and watch the pin while he listens, he will, if his observation corresponds with mine, recognise the first movement of the pin at the beginning or in the early part of the murmur. By this showing the murmur does not precede but begins with the systolic movement, and is not presystolic but systolic.

organs are damaged, and well is it for the man who has the physician for his friend to help him how to arrange his life.

The effects of sudden moral shock are known almost as well as those of physical concussion; but the long-continued wear and tear of a life, distracted by a conflict of emotions, is often unsuspected or unrecognised until it is too late.

Hysteria, melancholia, paralysis agitans, a confusion of ideas and purposes when any attempt is made to use them—what I have called a mental and moral chorea—through incapacity of mind, and loss of all decision and precision of thought, are the most common events; but with this there often comes as well some strange moral perversion, taking the form of extreme melancholia and self-accusation most frequently, but occasionally running into another still more lamentable state—viz., that of general paralysis of the insane.

The only excess of physical exertion to which I will allude now is that of such kind as shall embarrass the heart and nervous system. There are no physical exertions which in themselves are necessarily detrimental to the heart. Rowing, riding, walking, running, climbing, in reasonable moderation or only occasional excess, are beneficial, and highly so; but when the amount of necessary exertion is compressed into a deficient amount of time, then it becomes mischievous. The heart has its own special relationships to time, and if these are seriously or persistently disturbed both functions and structure suffer. An exertion which quickens the pulse and respiration may be harmless if within certain bounds; but if the eyes become prominent, the face flushed, the lips livid, and the extremities cold and dusky, the danger-point is reached. The line is an easy one to draw, but a difficult one to keep. Yet I am sure it is not out of our power to help. Many cases of heart strain may be greatly relieved by rest, and it is by violent, rather than continued, over-exertion that the brain becomes gravely affected. But too prolonged or too extreme an amount of physical exercise has its victims suffering from weakened arms and legs, and other evidences of spinal exhaustion. The fatigue of excessive muscular exertion upon the nervous system is seen in loss of sleep and appetite on a small scale; but its effect upon armies on the march has been seen in an increased frequency and severity of traumatic tetanus and other affections, partly induced by worry, defective food and clothing, and often by accompanying depression. Epilepsy, chorea, paralysis, and the like I have often found to date from physical fatigue, and to have their recurrences almost invariably traceable to the same cause occasionally brought into play.

That which we denote "preventive medicine" when applied to individuals, becomes general "sanitary science" when we have to deal with masses; and it is only by a careful scrutiny of all the *causes* of disease that we can render that science as efficient as it ought to be. It has sometimes happened that researches in one direction, and for the attainment of one end, have been unexpectedly the means of throwing much valuable light upon cognate or outlying matters—such, for example, as the relation, almost accidentally discovered, between the drying of the soil in sundry towns and the diminution of phthisis; but in the main it has been by earnest, planned, and persistent industry that the great achievements of science have been possible.

Life is lengthened, its existence rendered less painful and more hopeful, and its ailments so much reduced by what has been already accomplished, that—given what is wanted in time and in freedom of research—there seem to be scarcely any limits to the good that we may predict for future generations. Diseases, our enemies, one after another may be diminished, rendered harmless, or stamped out of existence. The adaptation of man to his environment may be so greatly improved, his frame so fitted to resist not only disease but natural decay, that its pains and weakness may disappear and be remembered only in the history of evolution, and thus its inevitable end may be without either suffering or fear. The moral nature may be so attuned to its highest faith, and so free from fret, sorrow, or remorse, that death will be welcomed as was birth, for the last "enemy" that shall be destroyed is death; destroyed—i.e., by being no longer our enemy but our friend.

AT the Guildhall Police-court, on the 22nd ult., a Trowbridge butcher was fined £10 and £3 3s. costs for sending to the market the carcase of a cow which was unfit for human food.

Remarks ON THE PRESYSTOLIC MURMUR, FALSELY SO CALLED.

By W. H. DICKINSON, M.D., F.R.C.P.,

PHYSICIAN AND LECTURER ON MEDICINE, ST. GEORGE'S HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN; HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE.

THE title of this paper will be an indication not only of its purport, but of the hardihood of the writer in daring to take into question one of the accepted canons of cardiac medicine. In so doing I am mindful of the consensus of opinion against me, and ask a hearing only after having long held the views I am about to express, and having often reconsidered and tested them.

The present theory of the presystolic murmur appears to have been introduced, together with the name, by M. Fauvel,[1] in the year 1843. M. Fauvel attributes the use of the term to M. Gendrin, but though M. Gendrin uses the words *prediastolic* and *perisystolic*, I cannot discover the word *presystolic* in his book, and I observe that Dr. Balfour has been equally unsuccessful in this respect. But, however originated, this theory owes its place in the medicine of to-day, with its almost universal acceptance, chiefly to the great authority of Dr. Gairdner of Glasgow. The view of Dr. Gairdner and of general acceptance is this: At the apex of the heart there is an intense rough, often rumbling murmur, which immediately precedes the first sound; in common phrase, it "runs up to the systole," the sound of which follows it without an interval. The systolic sound which follows the murmur thus inseparably is abbreviated and sharpened so as to resemble the second sound, from which it is distinct. This murmur, together with the altered first sound, is represented by the letters *R-r-r-p* or *V-o-o-t*; this murmur, together with the first and second sounds, makes a dactyl, — ⏑ ⏑; whereas the normal action of the heart is a trochee, — ⏑. A superficial thrill or vibration often accompanies the murmur, presenting itself at the same time and more or less in the same place.

So far there is, I believe, no difference of opinion; but I now enter upon ground which I regard as debatable. The murmur is held to precede the systolic movement as well as the systolic sound; it is held to occur during the expansion, not the contraction, of the ventricle, and to be produced by the passage of the blood out of the auricle into the ventricle through a narrowed mitral orifice. The murmur in this aspect belongs to the auricular systole not the ventricular; the force behind it, by which chiefly the sound and the vibration are developed, is the contractile power of the auricle. Some of these propositions I am about to dispute, but there is no possibility of doubting the practical outcome. The murmur which has been thus described as presystolic is pathognomonic of mitral stenosis. If the theory is to be judged only by the correctness of the diagnosis which follows from it, it must be correct. But a sum has been known to prove, notwithstanding, that errors have crept into the working of it. "His conduct still right with his argument wrong" may be a clinical as well as a social experience.

The view of the so-called presystolic murmur of which Dr. Gairdner was the exponent,[2] however generally allowed, was taken into question by some. The late Dr. Ormerod,[3] in the year 1864, disputed the auricular systolic character of this murmur on the ground that the auricular contraction was too weak and brief to cause so loud a sound, which he held rather to be due to the contraction of the ventricle, and to be regurgitant. At the same time he pointed out the difference in character between the "direct mitral murmur, such as is generally admitted to be of this nature," and the murmur under consideration. Dr. Gairdner,[4] in reply, "hesitated to affirm" what he nevertheless decidedly suggested, that the "direct mitral murmur" referred to by

uprooted by iron or food, or fresh air, or any other means save that of light; and we do well in prescribing this early in the anæmia of night-working men. The exposure to excess of light may be mischievous to the eye in many ways, but the prevention of such trouble is obvious—viz., the avoidance of such exposure. But the great majority of cases of "insolation" are to be traced to the co-operation, with exposure to light, of excessive heat, bad air in tents, and barracks, unfit clothing, and irregularity of habits, together with over-exertion and early neglect of symptoms.

(*c*) Electrical disturbances of health, such as occur in electric and magnetic storms afford much interesting matter for examination, but they are of comparatively rare occurrence, and are often susceptible of explanation by mental and moral rather than physical conditions.

(*d*) There is, however, another, very common source of discomfort and disease increasing year by year in this restless age: I mean that of physical concussion of the body as a whole, or of its parts. "Accidents" show us what violent concussion may effect in one moment; but daily life points out a more serious danger than accident can do. A great amount of shaking and knocking about may be borne by some with impunity, but there are hundreds, nay, even thousands, who are now steadily, slowly, but surely damaging themselves by constant travelling, and especially by railway. Such travelling is often accompanied by hard work, much worry, and exposure to the changes of temperature, which make up what we are pleased to consider as, and call, "our climate." But beside and above all these, the mere recurrence of shaking or "shock" is observable enough. The most prominent effects are irritability of temper, restless fatigue, want of power of application, defective memory, want of confidence, and want of judgment, with insomnia or uneasy sleep, and depression of spirits. The jar of frequently stopping suburban trains is more commonly and quite as seriously damaging as are the occupations which lead men to travel many hundreds of miles per week. Crying children, who will not be rested by a gentle rhythmic movement, may be shaken to something like sleep by a vigorous nurse; and so may the busy man who, paper in hand, jumps into a first-class carriage at the end of a day of work and worry, and is concussed into a sort of coma by six to seven minutes of the train. In the early stages of such troubles some modification of the daily mode of transit may be of service; but when the discomforts have gone to the point of destroying sleep, appetite, and relish for work, nothing but an absolute cessation of the travelling is of the smallest [illegible]

B. The next great group of causes of disease may be put under the one head of modified expenditure as compared with income. There must be in health an outgoing of both material and of energy; and disease is actually present, lurking near, or very easily brought in when arrest of excretion is present.

1. The excretion of *material* is as essential as its introduction. (*a*) Arrest of "excretion" introduces "local" troubles, which tell back and limit "secretion," and this latter limitation becomes at once a "general" or "constitutional" disease. Retained cutaneous excreta produce acne and miliaria; arrested secretion may be followed by pleurodynia, sciatica, local paralysis, pleuritis, or any other inflammation. So with the urinary organs. Arrest of excretion affects the bladder and the kidneys by a backward action, but the non-action of the kidneys places life in imminent peril from toxæmia of most urgent sort. So with the bowels,—habit, laziness, shyness, or what not, may lead to hernia or apoplexy by the straining they induce; but more frequently hæmorrhoids, accumulations of fæcal matter, and their consequences, are the immediate result; but if the intestinal *secretion* be either arrested or misdirected, then grave constitutional disturbance is present or at hand. The same principles hold good with regard to all the systems of the body. The physician has to guide with regard to "excretion"; but common sense about matters that are mere "pathological pap" to himself he will find absolutely wanting, and its dictates quite unappreciable by otherwise well-informed and capable men and women, as well as by boys and girls. Want of attention to "excretion" may be long concealed, but a suppressed "secretion" at once places the patient in the doctor's hands. General medicine may do much for both, but its true *rôle* is in prevention.

But (*b*) evacuations may be excessive, and these of either blood itself, or of other fluids containing it, or its main elements in large proportion. It is enough to mention the drain of hæmorrhoids or of menorrhagia, the exhaustion of chronic diarrhœa, diuresis, or diaphoresis, and leucorrhœa, to indicate the directions in which preventive medicine may do its best, only again emphasising the common fact that these things have often to be looked for to be discovered, and then some considerable discount allowed as to the accuracy of statements made from either delicacy, the wish to be let alone, ignorance, or the "little knowledge" carried to the point of "danger," conceit, caprice, or stupidity.

2. In controlling the amount, quality, and conditions of "expenditure," in *mental, moral,* and *physical* directions, the physician has a wide range of work. The elimination of force is as important as is that of matter. There is, on many sides—mental, moral, and physical—a tendency to meet excesses of one kind with excesses of another. There is a "polarity," so to speak, in society, to be seen in the way and degree to which over-work goes along with—I cannot say begets—under-work; mental strain is associated with mental idleness; eager attempts to solve moral and social questions by something more rapid than a motto of mere *solvitur ambulando* impotence, side by side with the lazy *nil admirari*, provoking egotism and uselessness of full-blown or unripe swelldom; while at the same time the training of the physical athlete is seen in heightened contrast by glancing at the waxy, cumbrous, dull stupidity of those who take no bodily exercise beyond that of lounging in the carriage or the club, diversified only by the too-frequent cigarette.

(*a*) Defective mental occupation begets—by way of bad hours, alcoholism, a love for poor literature, and self-indulgent habits—silliness, self-consideration, egotism, hysteria, hypochondriasis, and progressive feebleness of mind, memory, and understanding. Ten talents may earn another ten; or, *per contra*, they may be abused or lost, with character to boot, by simply being laid aside or hid in a napkin; for it is not the man with *one* talent only that may call upon himself the strong disapprobation of his Lord. To use the powers we have, and incite others to do the same, is a part of our work in the prevention of disease.

Again, the moral nature of man and of society may be stunted, misapplied, or blotted out by simple indolence. How often do we not meet with people who care nothing for anything or anybody but themselves; who read both sides of a debate, a philosophical dispute, or a police report with a languid indifference, and without ever caring to exercise their own thought as to which is right or wrong, "because it's such a bore to make it out, don't you know,"—until, by steady practice of not using the brains he has, his one little talent has shrivelled up, and when he may, perchance, try to turn it to some account, he finds that somebody or some conditions have put a brass farthing in its place. This don't-careism of young people so common now may be somewhat improved by parents and tutors, but it is the physician who will do more than either if he uses his opportunities aright.

The mere allusion that I have made to the deficiency of "physical" exertion, is enough to point out the true line that preventive medicine has to take. It is not so much in youth as in middle life that its effects are shown, and our powers are often limited to the diminution of troubles as they occur, rather than to their prevention beforehand.

(*b*) In this part of "the nineteenth century" we come into contact with excess of work—mental, moral, and physical—on almost every hand. But let us, so far as consequences to health are concerned, at once distinguish between work with worry and work without; which comes almost to mean voluntary and involuntary exertion. Work does not hurt much, worry does. Some are put to learn or do things that they are unfit for, and they suffer. The work may be of the kind that they cannot do, or the amount required may be out of proportion to their strength. Some men can no more learn mathematics than others can music. There is a *Pons Asinorum* somewhere, not only in Euclid, for almost everyone, and much trouble of school, and college, and after-life might be entirely spared if relatives and tutors would recognise the fact.

Mental work is not excessive if the appetite be good and the sleep sound; if these be interfered with, the student or the athlete (in muscle) is doing too much. Work for its own sake is beneficial, but under the pressure of an examination looming in the distance, or of some panic in business, work, to get over the difficulty, is often made excessive, and then worry comes on, with its train of physical troubles that attend loss of appetite and loss of rest. The functions of all

Digitized by Google

down" occurs, and relations and friends exclaim, "This is quite too terrible; he seemed so young a man, and was only yesterday quite busy at his work, and full of life and schemes." He ought *not* to have been busy at his work.

As in babyhood we are exposed to the wills and whims of others, to carelessness, stupidity, or over-fussing, to bad feeding, neglect, or exanthemata, to tumbles, broken legs, or other frivolities; so, later on, when the romantic period of youth—be it for learning or for play—has done its best or worst, and *early middle life* begins, the exposures fraught with danger are those of over-excitement and over-work, and against these the physician knows only too well how much he could do if the patient would but hear and follow. We pass on to *middle life*: sometimes a wholesome table-land, but often a still arduous, too arduous climb, or a slow decadence of failure and dismay; and we see success leading to excess on the one hand, or failure plunging into dishonesty or despair upon the other, and here to we must again warn in time; and as the life goes on to its *second infancy*, through an emotional epoch of pitiful weakness, a senile hysteria, the physician has again to use all his care to see that he who has outlived all those who gave him joyous welcome to his cradle is yet tended as he should be, and piously cared for to his shroud.

There is no stage of life at which we are not wanted, no age when we are without anything to do; and let us be ever mindful of our high responsibility of foresight, being assured that in the vast majority of instances we, in spite of many prejudices, shall find ready adjutants thankful for any hints that we may give; and, by doing our work well, be spared having to frame an answer to the terrible question —sometimes quite fairly put—"Why did you not tell me this before?"

D. Temperament is a word more frequently used than analysed; and although its striking forms are known to all, it sometimes happens that its influence on the tendency to disease is disregarded until the disease is brought about. The physician, however, should be on his guard, and try to prevent the *sanguine* youth or man from relying too complacently on his energy—which may not always mean strength,—and so protect him from the consequences of undue hopefulness, carelessness, and from many troubles he had not in the least degree anticipated. On the other hand, the *phlegmatic* may have their morbid proclivities lessened or removed by timely warning and rousing to a sense of duty; while the *nervous* may be strengthened against their trouble by the wise counsel of the physician, who may have the art of obtaining confidence and speaking with authority.

II. I come now to the *second* great group of "causes of disease," to which I alluded at the outset—viz., the disturbances of the equilibrium or balance between the necessary elements of income and expenditure, whether these be of matter or of force. It is absolutely necessary for health that we should "take in" certain things and forces, and that we should "give out" others. It is also essential that what we "take in" should be wholesome, and conducive to healthy life. This range of subjects is so wide and varied that I can but enumerate some of them, and point out generally wherein the physician can act in the prevention of disease.

A. Income is both material and immaterial, or ponderable and imponderable; we need food and air, light and heat on the one hand; excretion of material, and exertion of nerve and muscle on the other. These should be balanced, or we are not in health.

1. The *income* of matter involves all that is included under the head of "Food"—solid, liquid, and gaseous—which may be either defective or excessive in quantity, or wrong in quality. The absence of certain elements—such as vegetables, for example—has its entail of scurvy; while deficiencies of either the albuminous, amylaceous, oleaginous, or saline elements produce their specific morbid changes. Deficiency of food of all kinds is often, too often, sadly, the cause of multiform maladies; associated, as it almost invariably is, with other anti-hygienic conditions, such as over-work, over-crowding, and intemperance. Excessive feeding, on the other hand, which at last brings its own remedy in loss of appetite, may, on the way to that stage, produce a hundred maladies of every organ in the body.

But the great source of disease, against which preventive medicine has shown its strongest powers, and with which it now wages war the most vigorously and incessantly, is the introduction of noxious matter, either with food, by the air we breathe, or by direct inoculation. The appliances of science have done much to diminish the evils that arise from the metallic or other poisons, such as lead, mercury, antimony, steel, phosphorus, and the like; and the mode in which good has been obtained is by the prevention of their entry into the organism, and also by rendering assistance in their excretion. In like manner, the more subtle poisons, which are the physical bases of all zymotic disease, are to be robbed of their power for mischief mainly by being kept out of the body. The physician has found out the sources of many of these poisons, as well as the modes by which they enter the body, and, having done so, has devised means for their arrest. The *materies morbi* has been separated from much that had surrounded it, and measures for its modification or destruction have been discovered and applied. Our knowledge of the definite importation of cholera, typhoid, and more recently of some outbreaks of scarlet fever, by means of water and of milk, and, further, the knowledge that by simply boiling these fluids the poisonous material is deprived of its power for mischief, afford grounds for hope that, by increased observation, the sources of other maladies may be found, and means for their destruction be devised.

The magnificent results that have been obtained and demonstrated with regard to vaccination and variola have stimulated the zeal of many enthusiastic workers, and raised—as almost all beneficial discoveries have done before—a perfect tempest of opposition, misrepresentation, and frivolous and irrelevant talk. The questions of syphilisation and of inoculation for rabies must be regarded as still *sub judice*; but a sufficiently strong case has been made out in regard to both these poisons, not only to justify, but to demand further inquiry.

2. There are certain imponderables, such as heat, light, and electricity, that we require for healthy life, and the deficiency in the income of which is the frequent cause of disease.

(*a*) We all need external warmth, and at the extremes of age the need is greatest. Many follies of habit may be rectified by the physician, even although in some individuals the constitution is so marvellously elastic that it can bear an amount of ill-usage that would kill many a race of animals. Whatever may be said of the process of "hardening" by exposure, it surely cannot be a universal advantage to undress under the trees of Hyde Park, in an east wind and drizzle, at 7 A.M., in the winter months, plunge into the half-frozen Serpentine, and get home to breakfast cold and blue, with chattering teeth, and exclaim with a mixture of pharisaism and apology in tone, "It is when it is as cold as this that it does you all the good in the world!" There is much "tubbing" and bathing in the present day that is excessive, unphysiological, and mischievous, and there are endless follies in the form of clothing that the physician can do little to cope with simply because there are two much more popular preachers than he—viz., fashion and fad. Excessive heat has some injurious effects in itself, but the really active sources of heat disease in hot climates are the malarial or other poisons which are there, and the injudicious clothing, eating, and drinking which in too many places are habitual. The occupations which expose stokers, furnace-men, and the like to intense heat may be rendered nearly if not quite innocuous by attention to clothing, to the length of exposure, to the full supply of water and of fresh air, and to the alternation of work done with periods of due freedom from exposure; these things to be arranged with knowledge of the wants entailed by special kinds of labour in individual cases. To the philanthropy of employers, and the zeal for all sorts of social improvements in a rapidly growing class of men, as well as to the labours of the men of science, are we indebted for the prevention of much of the evil that excessive heat might bring about.

(*b*) The absence or deficiency of light, and especially of sunlight, shows its morbid effects in the impaired health of miners, navigators, workmen in cellars, in city offices, and in the night. The night working to which I refer is such as must limit the income of sunlight to a considerable degree. Those who suffer most are the reporters, literateurs, printers, writers, and many others whose work is nocturnal exclusively, and who require some distinct changes to be made in their habits. Anæmia is the prominent mischief brought about by deprivation of light; and anæmia means very much—very much more than mere pallor of the skin. There is no organ in the body which it does not affect; it cannot be

Digitized by Google

converse condition of insusceptibility cannot be regarded as a morbid condition. Caution as to exposure is almost as important in the one case as in the other, for rashness is not without its victims, and to this allusion has been made already. Many precautions must be taken on behalf of those who have hereditary taint, for the conditions may be multiform which come together to produce from it the fully developed disease. As an example of popular knowledge on this point I quote a paragraph from *The Times* of Sept. 12th, in its review of Mr. Colvin's recent "Life of Keats." The writer says, after alluding to the eminently pugnacious character of the poet in early life, "It was not till the hereditary taint of consumption, which had already killed his brother, became developed by the over-exertion of a walking tour in Scotland, that pecuniary troubles, caused by a stupid and stolidly unsympathetic guardian, combined with the hope deferred of a long engagement to Fanny Browne, and perhaps to some extent the disappointment of literary ambition, fostered a certain morbid tendency of his nature, if the term 'morbid' can fairly be applied to a turn of mind to which literature owes some of its greatest masterpieces."

B. Sex has always found its place among the "predisposing causes of disease"; and if general etiology were the theme of this address there is very much that ought to be said regarding it. But as the physician has no power to direct the production of boys or girls respectively, all that preventive medicine can do is to guide the development of each. Organs must be present to take on morbid action, but the *differentia* of sex are far wider than the possession on the one hand of ovaries, and on the other of testicles. The moral, mental, and physical conditions and aptitudes of the two sexes differ; and while civilisation has intensified, through generations, these *differentia*, the tendency of much recent fashion—I cannot call it civilisation—has been to diminish them: so that we encounter on every hand manly or "masculine" women and effeminate men. In uttering its protest against this perversion of nature, this devolution instead of evolution of the race, preventive medicine may be of service.

There is nothing to my mind more simply silly than the "cant" or "slang" that has been uttered about the "superior" and the "inferior" sex. Each may be perfect in its way, but each is spoiled when it apes the other. In rough conditions of life women may have been, and are now, better fitted for physical labour than are those whose very configuration and faculties have been modified by social habits of refinement; and it certainly is not the aim of the obstetric physician, either man or woman, to encourage the development of the "masculine pelvis."

It is worthy of note here that it is not the highest qualities of man that young women imitate, but rather, on the one hand, the roughness of the youth, his bravado, and uncouth language; or, on the other, the lackadaisical *nil admirari* tone of the pedant and the fop; with, it may be, an occasional dash into imitation of excessive learning, and the habits of the ascetic or recluse. The men who mock women's ways also mock their foibles, not their strength; and lisp and sigh or groan out their unsatisfied longings in vapid admiration of sentimental nonsense, whether it be in poetry, music, or painting, and find out something "quite too lovely" in a line, a strain, or a daub, that no sensible man would care to hear or see again.

The brain of women is not improved by being roughened or overstrained; and the emotional nature of man is enfeebled by this reversal of the order of Nature; and we find the tendencies to disease inverted without any advantage to either. The physician may, I think, do much in counteracting this tendency of the present day: protesting, on the one hand, against all foolish pruderies, mock-modesties, and the like; and, on the other, encouraging healthy habits of body and mind; always bearing in mind that the highest type to aim at is the perfection of woman and the perfection of man, and not the production of moral and mental hermaphrodites, which, thank Heaven, are usually sterile.

Let it not be supposed that I do other than admire the great strides that have been made of late years in the higher education of women, both for intellectual and practical work. These may be readily overdone as they are in men, and very frequently the results of over-strain are seen in illness, incapacity, and distress. Their exhibition, however, is less painful than the frivolous inaptitude and idleness of men, who, with all social and educational advantages, do nothing, never occupy themselves with any calling or pursuit, but are content to "bide or loaf about" and live upon their incomes, or their friends as the case may be. Over-strained women often become sour and cynical and morbid, as do briefless barristers and unpopular parsons, who may have much laboriously gathered learning in their brains, but have no congenial work to do. They complain of like discomforts, "diminished brain-power," as the favourite expression goes, and entire dissatisfaction with everything and everybody. Under-occupied men become hysterical and silly, and the prey to every form of hypochondriacal misery. It is the highest sphere of man and of woman to be the complement of each other, and to combine in the work of home first, and then of all around it; but the work of the one should be a woman's work, and of the other, "all that may become a man." It is in the imitation of the ways of the other sex that woman becomes repulsive, and man despicable.

With regard to sexual proclivities to organic diseases, there is something for the physician to do in being forearmed. For example, the greater frequency of simple ulcer of the stomach, of erythema nodosum, goitre exophthalmica, and the like in women, and of angina pectoris, carcinoma ventriculi, locomotor ataxy, and other maladies in men, may be of service not only in diagnosis and prognosis, but in treatment.

There is, however, much that prevention may do by regulating the habits of boys and girls. In healthy exercise, the avoidance of over-strain of muscles and prolonged fatigue, in wholesome food and sufficient rest, and in a score of ways, many a trouble which might easily become developed into disease may be avoided. Many cases of heart and lung disease originate in the rough games of schools; many of the troubles of women in their indolent and unwholesome school-room and after life, in the follies of their dress, and the hours they keep.

C. Age. We know much, but understand little, of the time-ordered events of life. There is an average pulse and respiration time; there is the incubative period of life as well as of the exanthemata; dentition, puberty, climacteric changes, and decay have their relations, more or less fixed, with time; and a knowledge of the predispositions attending various ages may be of service in the prevention of disease. In infancy the thermogenesis is low and the capacity for digestion limited to certain kinds and quantities of food; so that danger lurks in defective clothing and defective feeding. There is rapid development, and the reflex functions are over-active, so that there is undue proclivity to spasm, not only of the voluntary muscles, but of the vessels; for spasm may cause infantile paralysis as well as infantile convulsion. Febrile conditions are common, and so are local disturbances of the circulation, such as internal congestions, and other forms of congestion not internal, such as chilblains. It is by regard to the nursery, the clothing, the food, and the surrounding conditions of domestic kind that the physician will ward off much disease.

In dentition—whether first, second, or third—the nervous conditions which precede as well as accompany the eruption of the teeth must be duly regarded and foreseen, and so many troubles averted before local discomfort of the gums has taken place.

At puberty it is by guiding the *general* habits of the individual rather than by looking after possible *local* troubles, by maintaining a healthy tone of domestic life rather than by special treatment, that the physician will do his best to prevent disease. We are too often disposed to be looking for some special sign of change, forgetting that "change" is always going on; and so, sometimes, we may let golden moments or months pass by unused. The follicle of the wisdom tooth may be found in the embryo jaw, and many of the evils of all the so-called "changes of life" exist long before any special events have made them obvious. Bearing these thoughts in mind, we may always see much to guide us in advising those upon whom "age" is stealing, but who have as yet had no warning that it is so, for they are "younger than their years." Those who are "older" often come quite soon enough, but rarely too soon, for help. The horizon of thought and work ought to be made smaller when memory becomes treacherous, arteries rigid, and the heart's impulse low. Timely caution, based on facts which only the doctor knows, or from the revelations made to him in his confessional—although carefully concealed at home,—might save hundreds of "shocks," or more slowly growing and increasing griefs, when some unlooked-for "break-

Digitized by Google

development of certain organs afford scope for the teratologist rather than the physician. They furnish illustrations of curious facts in heredity, and in this way are interesting and instructive, and may be useful. Hare-lip is so often the result of a mental impression made upon the mother, that the sequence of events cannot be confined to the chapter of accidents; the same is true with regard to supernumerary fingers or toes, and these peculiarities are liable to recurrence through successive generations. Observe here that the original cause of the deformity was not hereditary but accidental, and yet that it became hereditary. This question of the hereditary transmission of acquired habits or conditions is still *sub judice*, but to my mind many of the facts recorded by Darwin are susceptible of this interpretation, notwithstanding the very strong evidence afforded to the contrary by the history of the habits of the Mahomedans and Hebrews.

4. Morbid conditions of function or structure of particular organs or sets of organs, and such as do not affect the *general* health, are very commonly met with, and for some of them much may be done. These may be resolved mainly into organic changes which limit, or derange or destroy, functional activity. (*a*) The organs of special sense furnish the best examples of this class. Almost every variety of limitation or perversion of the sense of sight, from slight myopia to absolute amaurosis, seems to run in families. Sometimes the defects are congenital, sometimes they appear in adolescence, and again they may be deferred until declining years. It is in the early recognition of these maladies that the main hope of amelioration is to be found. Ophthalmic science is a growth of our own day, and its powers are now being used for the education and strengthening of the healthy eye; in the timely correction or removal of some sources of deficiency; and the supply of optical instruments to reduce to a minimum the disabilities with which some are born and which others acquire. Whatever may have been the prescience of our forefathers and their skill in surgery, it has been reserved for the latter part of this century to see "the blind receive their sight," and these not only among the favoured few but among the multitude; and still further, not as the result of any painful operation, or in the face of any risk, but simply by adding to a profound and scientific knowledge of the structure and functions of the eye the aid yielded by a mastery of the sister science of optics.

(*b*) Deaf-mutism, again, may be hereditary, congenital, or acquired, and some of the most astounding results of training have been witnessed in this field. A congenital deaf-mute, if left alone, becomes as a rule an imbecile; one who has been born with language and hearing, but has lost them both in early life, may become the same, if nothing be done to educate him, while the results of due teaching are marvellous. Two boys, brothers, were brought to me at about three and five years of age; they were congenital deaf-mutes and imbeciles, and examples of the same miserable condition were found in other members of the family. A very clever, most patient and persevering tutor was found for these boys, and when the elder was between eleven and twelve years of age he had been taught to read, write, and speak with accuracy. He could read not only from books, but from the lip or from the hand; could articulate very well; could parse a sentence in English and translate it into French or German! There are thousands in this country who have no advantage of this kind, and so they remain to the end of their days mere vegetating boys and girls, or men and women, a burden to their relatives and a disgrace to the community.

5. The fifth group of hereditary diseases is one so large that it seems to include almost all the maladies that flesh is heir to, except those that are the result of direct introduction of poison from outside. They are as numerous as the organs of the body, and as various as the possibilities of change. Such inherited ailments agree however, in their consisting of a general tendency to disturbance of varied functions and structures, and in their becoming expressed in the form of so-called diathetic or "constitutional" disease. If there are, on the one side, occasional examples of hereditary "nervousness," or simple epilepsy; there are, on the other, tubercle, scrofula, Bright's disease, and others about which it may be truly said, "the whole head is sick, the whole heart is faint, and there is no soundness in it.' Yet even in extreme cases preventive medicine has its work to do.

(*a*) The condition of ill-health most frequently met with in hereditary diseases of the nervous system is one of undue liability to disturbance;—given in any one of the antecedents of a particular individual, either insanity, epilepsy, hysteria, tendency to excesses, great nervousness, or what not, the outcome may be any other of the maladies mentioned, and not at all necessarily a reproduction of the initial disease. It is by bearing this fact in mind that the physician will see the necessity of being armed at all points. It is not enough to avoid or counteract the tendency to convulsions in the first dentition, the second, or the third; but other diseases such as chorea, hysteria, wilfulness, tricky ways, cruelty, and deceit must be borne in mind. No routine practice will be useful; it is often worse than useless. For example, a child at twelve becomes nervous and restless; his father had fits when he was young, and is an odd man now; some other members of the family had convulsions; an uncle was epileptic, and therefore this is regarded as a case for bromine, a diet restricted to insipid inefficiency, books are to be put aside, school abandoned, the boy petted and pampered at home in the bosom of his family, several of whom are somewhat queer, and so, in spite of bromide and of a redundancy of counsel, he becomes a victim to the very malady from which so much was done with the intent to protect him; and this, be it remembered—and the like has happened scores of times in my experience,—when the boy was simply anæmic, wayward, underfed, and not quite straightforward in his ways, and really required iron, not bromine; good food and plenty of it; the discipline of school, as well as its work; the companionship and the sports of his own sex, instead of the petting of his sisters and little brothers, over whom he tyrannised in secret, and so escaped the thrashing he deserved.

Another illustration of the like mistake is seen often in girls, whose mothers have passed through an early life of indulgent petting into one of hystero-mania, or ego-mania, and then gradually into that of chronic silliness, self-absorption, and the sacrifice of parent, husband, child, or friend to each and all of her foolish whims. "No one has ever opposed her"; "She has always had her own way": this is what we are told, and therefore she must go on as she has been doing, and her daughter must follow suit. There is nothing the matter with the girl except occasional migraine, from some real or hypocritical fasting, or from sitting up at night without food poring over a trashy novel. She can sit a horse, but she cannot sit upright in a chair; she can play lawn-tennis, but she cannot walk; she cannot sit out "morning church," but she can dance for five consecutive hours. "She is just like her mother," her relatives exclaim; "we dare not thwart her, or she will become as bad," and so she goes her own ways and fulfils their worst predictions. These are but common illustrations of the fault of thinking that hereditary disease must take its parent form; or of acting upon the presumption that, as the form is the same, there is nothing to be done. On the contrary, much may be done by taking patients from home and all its evil ways, giving regular employment of useful sort, exercise of mind and body, fresh air, good food, plenty of rest at reasonable hours, and utterly declining to admit the existence of anything but a slight malady that needs, however, definite treatment, and that of the kind described.

(*b*) Of gout, rheumatism, tubercle, scrofula, syphilis, cancer, Bright's disease, and many others, it is only necessary to observe that to be forewarned is to be forearmed; and that, when there may be a strongly marked hereditary taint, its development into disease may often be delayed or eradicated by timely care. We lose more lives through carelessness than through ignorance. May not the thin-limbed and thin-faced boy, with pink-and-white complexion, overtall for his age, who easily perspires and passes lithates, whose temperature and pulse run up quickly, who declares that he is very well until some general langour or local pain compel him to give in,—might he not often be saved from attacks of acute rheumatism, by careful habits, food, clothing, and medicine, and so spared all the troubles of a damaged heart? We have to look for these things, not have them thrust upon us. The day may be yet distant, but it will surely come, when regulated physical examination of the bodies of the young will be as necessary and as common as examination in the Latin grammar or the multiplication table, or other matters.

6. But there is another group of hereditary conditions, not common, but well marked—viz., a proclivity to "take diseases," sometimes of several sorts, sometimes of one only, for, e.g., such as scarlet fever or whooping-cough. The

ON
PREVENTIVE MEDICINE,

Delivered at the Congress of the Sanitary Institute of Great Britain, held at Bolton,

BY J. RUSSELL REYNOLDS, M.D., F.R.S., &c.,
EMERITUS PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE, LONDON.

THE causes of disease, with which preventive medicine has to deal, are so numerous and so various, that it is, first of all, necessary to arrange and classify them in some logical order. This I have attempted to do in the scheme which follows, premising that it is of provisional character only, and may be found useful as a working assistant until something better is propounded to take its place.

I. The first division is between those which are inherent in the individual, and those which are brought to bear upon him from outside. In the former category are to be found hereditary constitution, sex, age, and temperament; in the latter, all those influences which disturb the balance of income and expenditure of both material or ponderable and of immaterial or imponderable elements. Everyone has his life conditioned by the former. There is no possibility of eradicating the conditions, or of modifying them, when once developed in an individual; but their effects may be prevented from becoming disease by timely recognition and counteraction. Everyone, on the other hand, requires for the healthy performance of vital functions an equilibrium between the income of material—in the form of food, air, and the like—as well as the income of heat, light, and other forces, and the expenditure or excretion, or going out of material and of energy. Income may be wrong in quantity, or unwholesome in quality, while outgo may be at the same time defective; and so to the introduction of new poison from without is added retained poison from within. It is by the recognition of these causes of disease, and the employment of all our antagonistic powers, that preventive medicine may presume to be scientific in its method and successful in its results. The first of the inherent causes of disease is—

A. Heredity. There are many conditions passed down from one generation to another that are not morbid, such as configuration, height, mental and moral qualities, which are said to "run in families," but with which we have nothing to do here. But there are others which are morbid, and with the influences of which we have to cope, and if possible to intercept. They may be arranged under the heads of (1) redundancy or (2) deficiency of organs; (3) arrests of development; (4) unhealthy conditions of function or structure of particular organs or systems of organs; (5) disturbances of the whole body, diathetic, constitutional diseases, the tendency to which does or does not show itself until different epochs of life, when specific trophic changes occur; and (6) special proclivities to "take diseases" coming from outside; and, conversely, insusceptibilities of analogous kind, which latter cannot be regarded as morbid, but which may sometimes prove traitorous if relied upon too implicitly.

Speaking generally the power which the physician has to diminish hereditary disease lies in two directions (*a*), the forestalling of morbidity by the prevention of ill-assorted marriages; and (*b*) the special guidance of tainted children by all measures that can be used or devised for the purpose, by controlling moral, mental, social, and physical education, and regimen of life. This must be commenced before birth, continued in the nursery and school room, and maintained during manhood, and even to declining years.

(*a*) Marriages of consanguinity, even when there may be the very rare event of freedom from all taint on either side, are well known to become, in the second, third, or fourth generation, the source of much deformity and misery—and this in spite of all special statistics to the contrary. Marriages of consanguinity unfortunately "run in families," and so intensify the evil; and they are doubly difficult to circumvent—first, because of the primary bias to their contraction, and then because the poor creatures thus produced are specimens of nature's workmanship in its most untidy mood; features have rarely been duly chiselled, the sense of beauty has long been dead, while *gauche* figures and manners often render the victims little short of repulsive to all but those who, born under like conditions, have their faculties of perception so maimed and blunted that they know no better, and are also debarred by their own defects from making any higher choice. This is but a feeble account of what occurs too frequently when some distinct hereditary taints do exist in a family, and where marriages among its members have been permitted. Definite disease, as well as deformity, is the too frequent result; and the result is both persistent and aggravated until, happily, sterilisation may set in. No one can doubt the power of "artificial selection" in the production and perpetuation of advantages or peculiarities that may have been accidentally or artificially brought about. No one can doubt the force of "natural selection" along the lines of utility and the most consummate art; and no one can fail to see, or ought to fail to see, that there exists in man the power to modify the race to which he belongs; and acting up to his highest light, in all the paths of knowledge, to use his art to diminish or destroy that which has within it, at its beginning, the seeds of its own inherent decay, being assured that if he does his work well, nature will internally perform the rest. Conversely, every change, accidental or inherited, which limits the capacities of life, is liable to become fixed by transmission through successive generations.

But (*b*) there are marriages taking place daily, not those of consanguinity, but of unhealthy people, and of those who are actually suffering from developed disease, of marked hereditary character, or from as yet undeveloped taint, and that this often happens when the taint is very strongly exhibited in other members of the family. Let it always be remembered that hereditary taint, although undeveloped, is in itself disease, and then the grave character of the responsibility of propagating it may be, if not duly, approximately gauged. The function of the physician is to examine carefully and advise discreetly. He must weigh *all* the parts of the family history,—and here he will meet with the greatest difficulty, for often the facts are not known, or, when known, are either concealed or misrepresented. He must form an opinion of the intensity of the hereditariness in each particular malady, and also in the family under consideration; and he must have the courage of his convictions. This may make him unpopular or hated, but he must be strong enough to do his duty, and find in doing it his reward.

But it is in a very small minority of cases that preventive medicine is ever called into operation in this early stage. The minority is as small as the majority is vast in which the physician is consulted before disease has advanced into open and obvious activity. The devices that must be employed to prevent the development or further progress of inherited disease are as manifold as the affections themselves, and some further insight into the prevalence of the latter may be gained by a simple enumeration of those which are the most familiar. But here let me make two remarks by way of caution. First, there is no disease that has yet been shown to be *always* hereditary in its origin, so that, e.g., when we meet with insanity or phthisis in an individual we are not at once to conclude that it was "inherited" by him because a parent had been epileptic, or a grandparent had died of consumption. A large proportion of hereditary diseases can be traced to no hereditary source in particular individuals; therefore we must allow that, in a large number of cases where the possibility of inheritance is patent, a certain number may have developed the disease *de novo*. Secondly, with regard to many people the anti-hygienic conditions and habits which have led to disease in their ancestors may be persistent as cherished heirlooms, and be effective for mischief now. Especially is this the case with regard to the large group of diseases of the nervous system. There is much more than the mere physical contamination by descent in the etiologic conditions of a boy or girl who may be brought up in constant association with an idle, self-indulgent, hypochondriacal, or drunken father; and it is quite impossible to over-estimate the dire misfortune to a girl of being educated by an hysterical mother. No high powers of the microscope are needed to discover the *modus operandi* of the *materies morbi* of the contagium of "bad example."

I pass now to some special examples. (1) The redundancy, (2) the deficiency, as well as (3) the arrested

Remarks
ON
THE PRESYSTOLIC MURMUR, FALSELY SO CALLED.

By W. H. DICKINSON, M.D., F.R.C.P.,
PHYSICIAN AND LECTURER ON MEDICINE, ST. GEORGE'S HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN; HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE.

(*Concluded from p. 653.*)

If, then, what is commonly held to be a mitral obstructive murmur is not one, is there no such thing? If such a thing there be, it has been of late neglected, pushed from its stool by the "presystolic" murmur, which I have ventured to regard as falsely so called and erroneously interpreted as regards the direction of the blood. The auricular contraction and the obstructive mitral murmur (if there be one) must be simultaneous with the expansion of the ventricle. The ventricular systole is succeeded by a period during which this chamber remains closed and still; this by expansion of the ventricle and auricular contraction. The position of the second sound is important as marking time. This succeeds the first after an exceedingly brief space. The sigmoid valves are closed by the elasticity of the aorta almost directly the active contraction of the ventricle is over. But not yet does the blood begin to pass from auricle to ventricle. There is the period during which the ventricle waits empty and still. Not until it reopens can the blood enter from the auricle, or any murmur arise which belongs to this act. The murmur of mitral obstruction must therefore succeed the second sound with an interval. And it is obvious that there must be another interval between this murmur (if it exist) and the ensuing first sound, or any sound which is produced by ventricular contraction. The machinery has to be reversed, the dilatation of the ventricle has to be replaced by contraction, the muscle has to harden and pull itself together and stop the influx before it can get way on the departing blood. Thus between the auricular discharge and effective ventricular effort a certain time must elapse and a halt or break occur. The mitral obstructive or auricular systolic murmur must needs therefore begin after the second sound and end before the first, not "running into it," but distinctly separated from it. Such a murmur must be feeble, as is the auricular contraction, and it may well be, considering the want of *vis a tergo*, that it will be developed only in circumstances especially favourable to it.

Such are precisely the characters, as I have fully satisfied myself, of the true mitral obstructive murmur; and if this be so, cardiac diagnosis has in this matter followed somewhat of a planetary course, returning to the point whence it started some fifty years ago; but it has not come back empty handed, for it has acquired the art of recognising mitral stenosis with practical certainty, though by means of a hypothesis which is open to question. In the year 1839, Hope wrote as follows: "When the mitral valve is considerably contracted, a murmur (best heard in the same situation as the murmur from regurgitation, and distinguishable in the same way from semilunar murmurs) attends the ventricular diastole and second sound. From the weakness, however, of the diastolic current out of the auricle, the murmur is always very feeble, soft, like the bellows sound, and usually on a rather lower key than a whispered 'who.' I have found this murmur absent, unless the contraction of the valve was considerable, for the blood had still sufficient room to pass with tranquillity; and I have also found it absent when the contraction was *great*—when, for instance, the aperture admitted one finger only, or merely a quill, provided the current was preternaturally weakened by softening, by extreme dilatation of the heart, or by both. In such cases, however, the mitral disease would not be overlooked, as there is almost invariably a murmur from regurgitation. On the whole this murmur is exceedingly rare, though Laennec and authors in general have supposed quite the contrary from mistaking for it the murmur of aortic regurgitation. I have never known purring tremor to accompany a diastolic mitral murmur, the current being too feeble to produce it."[1]

Latham, in the year 1845, refers to the "mitral diastolic" murmur as indicating an impediment at this orifice, but as "a sort of clinical curiosity not found in practice." Watson, in 1857, recognises this murmur, and also its infrequency. "If the mitral valve be converted, as it often is, from a pliable folding valve into a long and rigid unvarying chink, the blood which passes through it from the auricle to the ventricle, during the diastole, may (though it seldom does) cause a rushing or blowing sound." Thus, the "mitral diastolic" murmur, small and infrequent as it is, was recognised by the older writers; and though of late its place has been usurped by the more obtrusive if less veracious "presystolic," yet the still small voice speaks as formerly, and occasionally finds a listener. Modern writers who accept the current view of the murmur which is called presystolic, yet recognise the old mitral diastolic. Bristowe, in his last edition, gives a diagram of each of these murmurs, both as significant of mitral stenosis. Austin Flint recognises two murmurs of mitral obstruction, the "presystolic" and the "mitral diastolic," the diastolic accompanying the early passive part of the emptying of the auricle, the other the concluding part, characterised by active contraction. Balfour holds similar views in this respect. Thus two murmurs, belonging, according to this belief, to different parts of the same act, may be separated by an appreciable interval; while two murmurs, the presystolic and the systolic, belonging to different acts, and made by the blood going opposite ways, may be inseparably blended together. This does not present itself with an air of probability.

Some of the writers I have quoted are among the greatest in medicine. To descend, I will describe the mitral diastolic or direct mitral murmur as it presents itself to my own ear and understanding. In a case of well-marked mitral stenosis where the characteristic *R-r-r-p* has indicated, as I believe, regurgitation through a constricted and ultimately closing valve, it is not very uncommon for one who looks for it to find in the middle of the cardiac pause a short soft whiff, brief, low, not abrupt either in beginning or ending, sometimes "a sound so fine that nothing lives 'twixt it and silence." This begins after the end of the second sound, and stops before the beginning of the first or of the murmur, which in such a case usually replaces it. If there be what is called a presystolic murmur, there is a distinct interval between its beginning and the end of the murmur which I am trying to describe. This murmur in time of occurrence resembles that of aortic regurgitation, though not exactly, for it does not replace or inseparably follow the second sound, but comes after it, usually with an appreciable interval. It is limited to the apex, which the aortic regurgitant murmur, often as it is heard there, seldom is—I must not say never. The direct mitral murmur is much lower in tone than is the aortic; it is not necessarily associated with the jerking pulse, or with what is called capillary pulsation, or with hypertrophy of the left ventricle, all of which are so well known as aortic concomitants. Notwithstanding these differences, there is reason to believe that the mitral direct has often been mistaken for the aortic regurgitant murmur, and possibly *vice versâ*.

To dwell for a moment on the differences and resemblances of the direct or diastolic mitral murmur and that of aortic regurgitation; if that in question be loud, intense, or accompanied with a thrill, it is certainly not a direct mitral. To be audible only at or close to the apex argues for a mitral origin, but not conclusively, since aortic diastolic murmurs are sometimes thus limited. I have endeavoured, but with imperfect success, to make posture a criterion. The aortic regurgitant murmur is commonly exaggerated by the erect position. I have seen cases, in which I have been practically sure that the diastolic murmur was mitral, in which it was audible only when the patient lay down; and it has been likewise observed with regard to the so-called presystolic murmur, which on any view is mitral, that this has sometimes been heard lying, not standing. But, on the other hand, I have found a similar variation with posture in murmurs which I thought to be aortic, though in cases in which mitral disease also existed. Upon this point more evidence is wanted, especially such

[1] Hope on Diseases of the Heart, third edition, p. 387.

Digitized by Google

as is completed post mortem; but it is not too much to say that the loss of a murmur with the erect and the recovery of it with the recumbent posture is an argument, though not a conclusive one, in favour of its mitral origin. The resemblance of the aortic regurgitant murmur under certain conditions to the direct mitral makes, indeed, the chief difficulty in the sure recognition of the less frequent murmur. This is of the greatest importance, because it so commonly happens that the typical contraction of the mitral valve is the result of endocarditis, which process seldom fails to traverse the small space from the base of the mitral valve to the base of the aortic, and cause some, though generally slight, thickening of the latter. Thus the aortic diastolic murmur is apt to present itself in cases of mitral stenosis, as also is the mitral diastolic. Often, perhaps generally, the distinction can be confidently made; sometimes it remains in doubt. The interval which usually separates the mitral diastolic murmur from the second sound is an important indication, as also is the aortic pulse.

A word may be added concerning the thrill which so often accompanies the so-called presystolic murmur. I believe, with Hope, that the current from the auricle to the ventricle is seldom, if ever, strong enough to give a thrill along with the direct mitral murmur. If a thrill accompanies a mitral murmur, I should regard this as a proof that the murmur is due to the action of the ventricle, and is truly systolic and regurgitant. A thrill may of course accompany an aortic murmur; it is common with the regurgitant aortic: but this is outside my present contention.

I will now relate three cases, one of which might have done duty in the earlier part of this paper, as presenting instances of the direct mitral or true auricular systolic murmur. The first two displayed this murmur in connexion with the common mitral regurgitant, the last with the so-called presystolic. In all there was extreme contraction of the mitral orifice. I would draw attention to the fact that the only case in which the murmur was what is called presystolic was likewise the only one in which, as seen after death, the valve could have been judged capable of closure.

Richard B——, aged fifty-one, was admitted on March 23rd, 1887. He had dropsy, enlargement of the liver, and the general symptoms of mitral disease. The præcordial dulness was increased in extent, the apex beat diffused, its greatest intensity in the fifth space slightly internal to the nipple line. At the apex were two murmurs, an ordinary systolic and a post-diastolic, the latter following the second sound after a short but appreciable interval. This murmur, like the other, was audible only at the apex; it was soft and ended gradually. The second sound, as heard at the base, was rather sharp, free from murmur. Over the ensiform cartilage was a second systolic murmur, which was interpreted as tricuspid. We had, therefore, murmurs which were significant of both mitral and tricuspid regurgitation, without the speciality which would suggest for either the term presystolic, together with the murmur which followed the second sound, and which I, in common with some of the older writers, believe to be the only true auricular systolic. During what remained of life the heart was made the subject of frequent observation. Occasionally the action was so irregular, with repeated short sounds mixed with murmurs, that it was impossible to assign any order to them; when the murmurs could be placed, they were always as described. The first murmur appeared to occupy the early part of the systole, though not ending with the abruptness characteristic of the so-called presystolic. The second left apex murmur which I have called post-diastolic (it should more properly be called *diastolic*, for it occurred in the diastole, though after the diastolic sound), always exceedingly soft and faint, was sometimes indistinguishable. The second sound also became weaker, and at times could be heard only over the lower part of the heart, below the nipple. The associated sounds and murmurs were best made out with a two-ended stethoscope, which brought the central part of the heart and the apex into hearing at the same time.

After increasing dropsy and hæmoptysis the patient died on June 15th. The heart was generally of large size. The left ventricle was dilated and hypertrophied, the columnæ carneæ much so. The right ventricle was dilated and much hypertrophied. The left auricle was thickened, the right dilated. The heart weighed twenty ounces. The mitral orifice was narrowed so as to admit only one finger. From the auricle the hole presented a crescentic shape about an inch and a quarter long, and half an inch at its widest. Its margin was here studded with rough lumps of stony atheroma. Towards the ventricle the valve narrowed; the curtains were greatly thickened with fibroid tissue, and adherent together at their edges, so as to make an irregular funnel shape, presenting below a much smaller opening than above. The flaps were not obviously shortened, and closure could be brought about, except at one corner, where a nodule of stony atheroma as large as a nut prevented their apposition and maintained a small opening while the rest of the valve was shut. The tricuspid valve was not altered otherwise than by dilatation. The opening admitted five fingers. The aortic valves were slightly thickened, but serviceable; they could not have allowed of regurgitation. The pulmonary valves were natural. It was sufficiently clear that there must have taken place both aortic and tricuspid regurgitation, while the narrowing and the roughnesses which beset the channel were such as to confirm the view taken during life that the diastolic apex murmur was one of mitral obstruction.

Rebecca A— —, aged forty-one, was admitted on May 18th, 1887, with the general symptoms of mitral disease, dropsy, bronchitis, and flatulence. The heart was apparently dilated, especially the right side. No murmur was as yet audible. The impulse was to the right of its proper position, the sounds quick, as with a contracted mitral valve, which lesion was suspected, notwithstanding the absence of murmur. Under treatment, chiefly small doses of digitalis, the heart became slower and steadier. On June 2nd two murmurs became audible at the apex. The first was a very low, barely distinguishable bellows sound, which accompanied the systole, went all through it, ended softly, and had the well-known character which belongs to the mitral systolic as distinguished from what is called the presystolic murmur. The second was post-diastolic, to use the word in the familiar sense of after the diastolic sound. A short, low, but distinct murmur followed this sound after an appreciable interval. The murmur was followed by another interval, which separated it from the systolic murmur, about to recommence. The second was regarded as the auricular systolic murmur of mitral stenosis. The sounds and murmurs were therefore placed thus: systolic murmur, second sound, interval, final murmur, final interval.

On June 21st the patient died. The condition of the heart was as follows: There was a great amount of fibroid thickening about the mitral valve, the orifice of which was reduced so as to admit only one finger. From the auricular aspect the slit presented a serrated edge, which seemed well calculated to engender a murmur. The flaps of the valve, of which the free edges were about an eighth of an inch thick, were so massive and rigid that they could not be got to close with any accuracy, so that regurgitation must have taken place, and, as it seemed, continued through the whole systole. The tricuspid valve was affected similarly to the mitral, but to nothing like the same extent. The aortic valves displayed one or two small beads of recent lymph on their ventricular aspect, which could not have interfered with their closure. Had a murmur resulted from these minute vegetations, which did not seem probable, it must have been obstructive. The pulmonary valves were natural. The left ventricle was dilated; the right dilated and hypertrophied. The left auricle was dilated and hypertrophied. The heart weighed fourteen ounces.

Charles R——, aged thirty-five, was on April 16th, 1886, referred to my care by my colleague, Dr. Wadham, as having a well-marked murmur of the kind known as "presystolic." This was perfectly characteristic: a short intense murmur at the apex was abruptly terminated by a shortened sharp first sound, this being succeeded by an ordinary second sound; the apex beat was very feeble, and scarcely sufficed to move the spring and lever which I made use of to mark the beginning of the cardiac impulse, but after several attempts I satisfied myself that the lever moved with the beginning of the murmur. The patient now left the hospital. He came in again under Dr. Cavafy, and was by him transferred to me. From February, 1887, until the following April, when he died, he remained under my care. It is not my present purpose to deal with the symptoms, but I may say, in brief, that he had increasing general dropsy, hæmoptysis, and finally incipient gangrene of the left foot. The sounds of the heart varied within certain limits. The action was often irregular. The so-called presystolic murmur was often present as described; latterly it was often so feeble as to be nearly indistinguishable, sometimes entirely absent. In addition to this, there was occasionally audible, but generally not, a short, low blowing murmur. A puff or whiff, which pre-

Digitized by Google

sented itself about the apex, was not to be heard elsewhere, and immediately followed the second sound, which itself was unaltered.

After death the mitral valve was found to be greatly thickened and narrowed by tough fibroid material, in which calcareous matter was embedded. The flaps were not obviously shortened, but they were adherent together laterally so as to form a nearly rigid irregular funnel, with so small an orifice towards the ventricle that it would not admit without force anything larger than the blade of a penknife. Towards the auricle, which was dilated and thickened, the opening presented a crescentic shape, the curved slit being about one inch in length and a tenth of an inch at its widest. From this, as its greatest opening, the channel narrowed to its smallest calibre at the ventricular exit. The auriculo-ventricular hindrance must have been extreme; it was, indeed, difficult to understand how the circulation could have been carried on. The valve flaps could be brought together by lateral pressure, though owing to their rigidity the closure must have been tardy and preceded by regurgitation. The left ventricle was of small size. The aortic valves were slightly thickened towards their bases, but were clearly efficient so as not to allow of regurgitation. The heart weighed thirteen ounces.

This case appears to have been one of double mitral murmur. As to the first, which was most characteristic of the so-called presystolic, I think it has been sufficiently shown that it was actually systolic with the modification upon which I have dwelt. The second or diastolic murmur, but seldom and feebly heard, was, I think, the true direct mitral or that of the auricular systole. The only point especially to note is that this murmur followed the second sound, without the interval which was noted in other cases, and to which I have attached importance. But notwithstanding this element of doubt, I think that, taking all the circumstances together, the murmur must be accepted as mitral rather than aortic.

In conclusion, I must recur to the meaning of the word "systole" as contraction, not sound. In this sense, I think, I have shown that the murmur is with the systole, not before it. If anyone is pleased still to call the murmur presystolic, let him do so, so long as he makes it clear to all that he speaks, not of the systole, but of the systolic sound. But if my contention be just, it will be best to avoid a term the use of which must involve an error either in observation or language. The point of practical importance which I submit is that the murmur does not belong to the systole of the auricle, but to that of the ventricle, and is therefore that of mitral regurgitation. The difference between this murmur and that of mitral regurgitation, as universally accepted, is chiefly in the modified first sound by which it is concluded, and the evidence thus afforded of the closure of the valve. It may be accepted as a general truth that a diseased mitral valve does not shut unless the orifice is narrowed; thus the so-called presystolic murmur becomes a sign of stenosis. For this great landmark of cardiac diagnosis we have to thank Dr. Gairdner. Our estimation of its value will not be lessened by any difference of opinion as to the precise origin of the morbid melody which we can so readily recognise, and from which we learn so much. Finally, I have endeavoured to rehabilitate the old mitral diastolic murmur, and restore it to its proper station as that of mitral obstruction and the auricular systole.

If the term presystolic is inappropriate, how is this murmur to be designated? We must call it something to distinguish it from the other regurgitant mitral murmur, the old-fashioned one, which continues through the whole systole and implies a valve that is always open. The "presystolic" might become "early systolic" in regard to its position in the systole, or the "stopped systole" in reference to its abrupt termination; while the other might be spoken of as the "full systolic," being unabbreviated and occupying the whole act. The feeble and infrequent murmur of mitral obstruction, the true auriculo-systolic, may keep its old titles, "direct mitral" and "diastolic mitral."

AT the Berlin meat examination station during the month of August there were examined 7945 calves, 11,788 sheep, 7216 pigs, and 8265 quarters of beef. Of these, there were condemned 17 pigs (including one from trichinæ) 8 from measles, and 4 from tuberculosis; also 3 calves and 9 sheep; 24 of the beef quarters, 8 of which were affected with tuberculosis, and 8 from jaundice; 62 lungs and livers were also condemned.

Introductory Address

DELIVERED AT

WESTMINSTER HOSPITAL

At the Opening of the Winter Session, 1887–88,

BY OCTAVIUS STURGES, M.D. CANTAB.,
PHYSICIAN AND LECTURER ON MEDICINE AT THE HOSPITAL.

GENTLEMEN,—When it was put to me that I should give the introductory lecture of this year, there seemed many and sufficient reasons for declining that honour. But amongst those reasons there certainly was not the want of a subject. I have always thought that the simple and obvious purpose of an introductory address is to introduce the student to his work. Its spirit should be that of which Mr. Black gave us example last year in words of cordial welcome and honest counsel which come so naturally from his lips. But there are some special reasons which this year bid us diverge somewhat from the beaten track. We are on the eve of grave changes in medical education. Whoever stands at this table next year will have to speak of measures by that time irrevocable, but which to-day have not passed beyond the stage of discussion. And the points at issue are so complicated, the interests concerned are so various, the conduct of the profession is so uncertain, that anyone occupying this place may fairly ask of his audience consideration and allowance in approaching a very difficult, but still a necessary, task.

Now, if I may be suffered to make a plunge where it is difficult to know how best to begin, I would class our present needs or defects in respect of medical education under two heads: one refers to the official tests of knowledge—the examinations; the other to the diploma or degree to be got in exchange for the knowledge so tested. The first want is a common standard of examination, and it is exemplified by the existence at present of some nineteen separate examining bodies. The second want is some appropriate designation or title for medical men which shall do away with the present invidious and misleading distinctions; and *it* is exemplified by the fact that there are now under consideration three, if not four, rival petitions, all designed to make London degrees more accessible.

As regards the first point—the examination standard. Has it ever occurred to you that a professional examination is no sublime or exalted institution? It is rather of the nature of a contract to which there are two parties. Each side makes conditions and gives guarantees. The examining body is responsible for the quality and completeness of its tests and for the public repute of its diploma. The candidate, for his part, attends lectures, produces certificates, and pays fees. It is a contract. But, unlike most instruments of that kind, the contracting parties are not equally watchful against infringement of the original terms. Penalty falls always on one side—the side of the candidate. As for the examiners, they may depart from the conditions by ever so much, and there is no one to call them to account. Thus they may exact too much, so that the candidate gets unfairly rejected; or too little, so that he passes unworthily. In either case the party examined is defrauded, yet without remedy. For if unjustly rejected, the complaint of the plucked is but lightly regarded, as being tinged with prejudice; and if too easily approved (although the wrong done to the student is not less than in the other case), it is not in human nature to criticise too severely the terms or the justice of one's own success. Yet, if you rightly think of it, is it not obvious that a strict observance of the terms of this implied contract is for the interest of both parties to it, and especially for the interest of the student? You seek to bring your goods—i.e., your professional knowledge—to the best market, where their quality will be appreciated and full value given in exchange. If the market tariff is uncertain, or the opportunity is denied you of making full display of your wares, or the price given for them is in a depreciated or obsolete currency, in any such case you strike a bad bargain, and are more or less wronged and defrauded. In plain words, if an examination is of no fixed standard, or the examiners are ill-skilled in eliciting or testing knowledge, or the reputa-

Digitized by Google

tion of the diploma is equivocal, the detriment is mainly yours. It is to prevent these bad bargains and to protect the purchaser that we have been long seeking (and hitherto in vain) to fix one standard of professional examination, and to exact a rigid compliance with that standard on the part of all the examining bodies alike. That is the main point. It is not all. There is still a higher education, both technical and general, and unhappily it is not within reach of everyone. As with our university degrees, this extra training must be reckoned by way of honour. It cannot be demanded as of necessity. Remember, too, that there is no order of merit whatever that examining boards can confer which can, or which ought to determine for good and all any man's place in the battle of life. Examination does not make up the whole of life, though it may seem to some of you that it spoils the best part of it. But the time comes when you are no longer tested by book knowledge, but by your ability in applying it. We must not leave that out of account. The main qualification for practice is that which practice itself brings to crucial test; and it may modify or even reverse the judgment of the schools.

I am speaking now of *technical* knowledge, and in terms that would not apply to education generally. Such adequate medical capacity as is needed for the whole community must seek its practitioners among many classes and be found in combination, now with more now with less of general culture. That is inevitable. The day is coming, we hope, when the higher education shall reach all classes alike. It has not come yet; and nothing is gained by pretending that it has. But although we cannot at present insist upon one uniform standard of general education, we can, as I believe, so insist as regards medical qualification, maintaining for all such high level of competence as shall be quite safe from depreciation or disparagement or any stigma of inferiority.

Yet some would have it otherwise. I have heard it argued in high quarters that the needs of the public, rich and poor, can never be fully met unless we make provision for an inferior order of practitioners—to be supplied, as is more than hinted, from the Apothecaries' Hall,—whose business it shall be to attend the needy, and stand between them and the wholly unqualified vendor of drugs. The proposal is a bold and a striking one. It is likely to be met without any special effort on our part. Inferior practitioners are never likely to fail us; we need hardly adopt the name as a professional title, or start in life with deliberate intent to qualify for that position. It needs no competition to reach the bottom, and no one is "ambitious of dishonour or an actual candidate for disgrace."

But what I would ask you to recognise is the utter futility and the public risk of all attempts to range doctors or diseases into classes of better and worse. It may be asked, "How else than by the agency of practitioners of an inferior sort can you reach the remoter parts of England, and bring medical aid to the distant and scattered homes of the poorest of the people? There is a simple answer: an inferior practitioner can mean nothing else than one who is ill-taught in professional respects. As such he is a source of danger, and not of safety. He not only discredits his calling, but hurts the public. I fully admit the alternative and know of the many evils of what is called "counter practice" by druggists. But "counter practice," bad as it is, is not half so bad as the blind treatment of an ill-trained, yet legally qualified, practitioner. And for this reason: "Counter practice," having no legal sanction or security, is cautious on its own behalf. The practising druggist is ignorant, but safe. He has no cloak for his ignorance, and no friends when in trouble. He works, so far as he knows, with our implements, and when danger threatens he ceases to work at all. But the ill-taught practitioner needs no such caution, and, to do him justice, he uses none. His diploma protects him, and his worst errors escape exposure by the operation of that complex code of medical ethics which shields every registered practitioner from the censure of his neighbours. But it is said, "Let us at least utilise such ability as we find." Let the less instructed practitioner have charge of the simple case, while more serious and complicated illness falls to the more learned. What, then, I pray you, *is* simple and what complex in disease? There is disease in the making, and disease ready made; that which you meet most in the out-patient room, and that which you meet most in the wards; and which is the more difficult? The fact is, that if any such division of labour as is here proposed were possible (which it is not), it would be the precise reverse of what the people suppose. Advanced disease shows itself, for the most part, by obvious signs easy to recognise. But the earlier stages of disease—disease at its curable time—is habitually obscure. And if medical skill were to be apportioned at all, it is not for the hopeless end, but for its early threatening, that we should want the best of it.

Now what I am pleading for by these arguments, this one professional examination, equal for all, and embracing all the licensing bodies everywhere, is just what this jubilee year is bringing us. It comes, indeed, not precisely in the way that was expected. It seemed at one time—or it seemed to some—that the "Conjoint Scheme" of the two Colleges would beat down all rivalry and become the great central examining body. For good or ill it has not so turned out. The Society of Apothecaries still survives, and still examines; for my part, I can see no reason why it should examine less well than the Colleges; at any rate, all those who looked to see the higher life of that trading corporation squeezed out of it must now reconcile themselves to a competition which the Apothecaries have it in their power to make both real and sharp. More than that, we must abandon, now and for ever, all hope that the licensing bodies of the United Kingdom will be reduced either in number or in the spirit of rivalry. Still, unless appearances are deceptive, the practice of one examining board underselling another, the spectacle of students going up and down the country in search of cheap and easy professional decorations, all this is under sentence of doom. And its destroyer is none other than the General Medical Council!

I am not confident that the mere name "General Medical Council" excites enthusiasm. I am not even sure that its precise function or use is known to everyone. Its debates are lengthy, and their cost (as Dr. Quain lately announced) is twenty-two shillings a minute. But besides its debates, it publishes annually a "Register"—a remarkable volume which, judging from my own case and that of others, represents the world as it stood in 1870. Of all official guides I suppose it is the least accurate. And, in fact, it partly lives on its own errors; for instead of being grateful for correction (like other Directories), it will put nothing right under a fee of five shillings. It only fails to mislead because no one ever thinks of consulting it. Nevertheless, this same Medical Council, chiefly known to us at present by its unsuccessful authorship and its enormous cost, has taken a step in the interest of medical education and examination, the importance of which it is really impossible to exaggerate. In our country revolutions are accomplished silently, and it may be that the recent appointment by the Medical Council of visitors or inspectors of examinations throughout the United Kingdom has escaped the notice of some of you. Yet, in our present circumstances, how better can we secure equal and sufficient professional examination than by the appointment of eminent men who, by periodic inspection and comparison, shall spy out whatever is defective in the quality or in the conduct of examining boards? *Quis custodiet ipsos custodes?* Who is there to examine the examiners? That question is now answered, and, with this new rule of inspection, examiners may be found wanting as well as candidates, and they will have to satisfy their own supervisors. Will they all get through? Have all the quality for eliciting knowledge, the patience to wait for halting answers, the forbearance that gives courage to the diffident? We shall see. Under the new order there may be rejections on both sides of the table. Altogether the bare contemplation of what is awaiting these new inspectors in their efforts to make all examinations fair, equal, and adequate, must crave our utmost sympathy and goodwill. We shall at the same time be properly curious for the first report of these officers, and, for reasons which the Medical Council will understand, extremely anxious that this great task of inspection to which it is committed should prove a reality. It would be affectation to pretend that the Council so far has greatly impressed the profession or the public. It has no great reputation to maintain; it has a stronger incentive—a reputation to make. All who have the best interests of medicine at heart—all of us here to-day—will watch its conduct of this matter with the deepest interest, if not altogether without anxiety.

And so peradventure it may fall to some of us, after these many years of waiting, to see this educational want supplied and a common standard of professional examination meted out to all. But what of the other want? Shall we ever obtain a suitable official title for professional use; ever be rid of these eternal disputes

Digitized by Google

about doctors and misters? I know full well that I am here treading upon delicate ground. It is easy enough to put forth general principles; it is far less easy to apply them. A number of persons starting from the same premisses will reach the most various conclusions; and the strange thing is that, even with much pains, it is often impossible to put the finger upon the precise place where the divergence begins. In what little I have to say upon the great M.D. question I shall not forget that by prescribed custom I have it all my own way for the moment. I shall not take your silence for consent, nor do I assume that there is but one way of stating the case. Yet there is one thing that may perhaps be taken for granted. We are all anxious to be M.D.'s; and the reason for that anxiety is that the public, even the educated public, owing to old associations and a natural reluctance to break with the past, are enamoured of that title, and believe, in a general sort of way, that a medical degree implies and guarantees superior knowledge. And from this position no argument can drive them. The actual facts have been explained repeatedly, but altogether in vain. They take our medicines, and much else at our hands, with a blind and touching confidence, but upon this one point they have so far insisted. That being so, what has been our own conduct—what is it now? Our present efforts are directed, no longer to removing, but to accommodating a false belief; accommodating it by some method or other which shall confer the Doctorate upon a more extensive scale than heretofore. It is very necessary, as I maintain, that this precise position of ours in reference to the title of Doctor should be kept in view. Much hinges on it. We might have dealt with the matter and with the public after a different and more direct fashion. This respect for a particular title is no worse than an anachronism. Doctors *were* learned men once. We might have had larger hope in time, waiting for a little, while the community at its leisure parted with the old beliefs and consented to surrender the obsolete. We might even by public pronouncement have protested against a delusion. We did none of these things. On the contrary, noting the mind of our clients, we are now about, not indeed to step over to their faith—it is not a faith,—but to yield to their prejudice and feed the idol of their superstition. It may be a good thing to do, and a politic, or it may be neither of these. Good or bad, it is what we are now about. And it is an indirect road to the desired object, which is certain to have perils of its own.

But someone will say, "Let the actual virtue of the symbols M.D. be what it may, the desire of London students to obtain a degree of their own, on terms similar to those which procure graduation at Glasgow or Durham, is perfectly legitimate, and ought to have been satisfied long ago. What is this pedantry that would stand in the way of our obtaining here in London, at the hands of the Royal Colleges, the very same decoration which, but for an accident, would have been procurable from a real London University?" Such language is reasonable enough, and I suppose there is no doubt whatever in the mind of anyone who has followed the discussions upon the subject that the want complained of—the want of a University—will be supplied. The question is, How? and I fear only too much in the breasts of some ardent spirits the question is, How soon?

It would be to little purpose now to relate by what accident, or series of accidents, it comes about that our vast city has no university of its own properly so-called. This Jubilee year fitly recalls the advance of medicine in many departments; most of all, I think, in that enlargement of its scope which places the public health, material and moral, among the concerns of the physician, making the progress of medicine all one with the welfare of the world. But for medical education the retrospect is less cheerful. University College to this day bears witness, by its name and the form of its government, to an abortive scheme which fell through on the very verge of accomplishment fifty years ago. And now, misled by a name, and in the belief that the examining institution in Burlington Gardens is in reality a university, the common saying is that what we Londoners want is a second university. "Why," it is said, "should a city more peopled than Scotland, of such vast treasure and resources, be content with a single university?" We are not content; and we have no university.

But while London has lagged far behind every city that respects itself, it is shaking off its lethargy, and the grand idea is beginning to take shape of a university so full and complete in all the requirements of modern science that the very thought of it is bewildering. And for years past, by its material development in art and science schools and museums, London has been preparing itself for incorporation as a great centre of intellectual training. Nor does it want for traditions not less venerable than those that enshrine the old universities. Tramping about London, I am often reminded that we have here, not our own merely, but the heritage of all the world. Old London, alas, is rapidly melting away. But there is hardly a street of it that does not recall memories that will never die. Take your way from the City to Westminster, and you leave Shakspeare at the "Mermaid" and Milton in Aldersgate; and, coming down Fleet-street into Covent Garden, you pass the lodgings of Goldsmith and of Johnson, the coffee-house of Dryden and Addison, the death chamber of Spenser, and the grave of the author of "Hudibras;" and so, by a barber's shop that saw the birth of Turner, greatest painter of the modern world, into Leicester-square, where, until late years, you had at a view Sir Joshua's studio, Isaac Newton's watch tower, and the workshop of our own John Hunter. There is no department of science, there is no school of art or of literature, there is hardly an invention or a discovery that has not had London for its home, if not for its birthplace.

All this, you may say, is fine talking; but we cannot build out of shadows or found a university of the dead. Such a work must take time, and we have no time to spare. There are corporations to be consulted; vested interests to be dealt with; conflicting claims to be adjusted. And, even when these are appeased, there is the University of London—the man in possession—to be considered. Your grand modern university is nothing but a dream. And so many of us have come to the conclusion that if we are to get help at all we must help ourselves. We have already a conjoint examination of the two Colleges; we shall have, we mean to have next, a medical degree attached to it. We shall be finished graduates while you are still dreaming.

"Your old men shall dream dreams." Yes; but let me remind you that the same scripture says, "Your young men shall see visions." Whatever our individual wishes may be, whether we favour or not this scheme of the Colleges for a medical degree, to be had on the spot and to be had soon, let us wake to realities and look the matter fairly in the face. Good or bad, the scheme is not unopposed. And the two petitions that are opposed to ours (that of the Teaching University and that of King's and University Colleges) speak with one voice. Listen to the words: "We deprecate any severance of the machinery for granting degrees in London from proper academic influences; any separation of the medical faculty from other faculties in the contemplated University."[1] It has seemed good to those who direct the policy of the Colleges to ignore these expressions of opinion. They have weighty support nevertheless. And, strange to say, among the active supporters of the opposing petitions are many leading members of our profession, who, but for this evidence, might seem by their silence to favour the scheme of their own colleges. It may be that in the end we shall accommodate the matter by mutual concession. It is much to be wished. But it is not as we stand now. The present proposals represent rival schemes. We cannot have all our prayers answered. One will be taken and the others left.

But suppose it done. Suppose that at the end of this year we learn that any candidate who has passed the conjoint examination is at liberty to go up for the degree of the two Colleges. Your first question in such a case will naturally be, What does "going up" mean; what extra subjects in arts or literature does the degree require? As yet there is no answer to that question, and no shadow of an answer. It has been asked repeatedly at the College, with no better result than to awaken those now well-worn chords as to the general excellence of the proposed degree whose music is now so familiar. I say that a large measure of the opposition to the Colleges' scheme is due to a wholesome fear lest this new degree should be conferred for professional attainment alone; that it should be used as a mere professional badge; and that thereby, however unwittingly, the position of medicine among the learned professions should be lowered.

But next comes this further consideration. You establish your new degree, and you set it down by the side of the existing M.D. of London. In so doing you must inevitably

[1] See Petition, Teaching University, p. 5; ditto, King's and University Colleges, p. 7.

Digitized by Google

invite comparison; and if that comparison is unfavourable to the Colleges' degree, is it not possible that even our master, the public, shall note the difference and signify it by some epithet of inferiority? Other Doctorates of other universities are what they are. There is the degree of this city and of that, each with its own reputation; but the degree you now propose is a degree for London. Its rank is determined by its locality; it is settled beforehand, and you can neither exalt nor degrade it. "People," it is said—and most truly it is the source of half our troubles—"people do not go behind names." But here, with two London degrees side by side, they *must* go behind. Rival practitioners will invite them behind. And if, upon this inspection, they find the one title demonstrably inferior to the other, your whole plan fails, and the similarity of title goes very near to suggest what lawyers call "a colourable imitation." Such dangers and difficulties can only be overcome by making the two degrees equal—equal, that is to say, from the point of view of the public, and regarded as professional tests. It is often complained that the Preliminary Scientific Examination of the present London medical graduates is unduly severe, and that thus the door is shut upon candidates who would gladly accept and be easily able to satisfy the later requirements of the degree. But where is the Council or the Government that would consent to a double set of medical degrees in London on the ground that one of the two made its own entrance too narrow? That would obviously be a case for reconstruction, not new creation. No. We must base our demands upon one of two grounds: either, first, that we desire a degree for London which shall be more accessible all round—that is to say cheaper than the present degree; or, secondly, that we desire not merely the form of a university degree, but the substance of a real university training. In the one case, the very terms of your demand are fatal to the repute of the new degree; in the other, it is not the scheme of the Colleges that you favour, but that of the proposed Teaching University.

And when the matter is fairly faced, I do not know that those who favour the creation of a real University of London as the best solution of the difficulty, impressed as they are with the unequalled resources of the metropolis and the unequalled benefit of that college comradeship which is the special ornament of our higher national training—I do not know that these have any reason for despair. Ours is a conservative country. Our university system is old, yet vigorous. It is an integral part of our social life, and must grow and develop along with it. It was never, in our long history, so active, so wide-reaching, or so popular as at the present moment. It is true that this new degree, at present undefined, is much belauded beforehand. It has all the perfections of the unborn (like the offspring of old maids and bachelors), yet it certainly involves an anomaly, its future status is at the best precarious, and it is not easy to deny that its main design is to meet and overcome a prejudice, and, indeed, a misconception on the part of the public. At any rate, let us know where we are. We are at least entitled to ask that this scheme of the Colleges should be presented in its entirety, and that its precise intention, as regards those branches of education which are not purely technical, should be plainly declared. Is it proposed that these new graduates, provided they show themselves well instructed as medical men, shall thereupon be deemed eligible without regard to the higher education? Or if that is *not* intended, then (inasmuch as the two corporations concerned have no art or literature departments of their own, as universities have), give us some express assurance—not by mere rhetoric or rhapsody (we have had more than enough of that)—tell us in precise phrase how much or how little of that general knowledge which just now goes by the objectionable name of "culture," how much of literature and of reading, it is proposed to include in the new qualification. And indeed, without being captious, we might go further and ask by what external aid the Colleges propose to conduct their examinations in art and literature, subjects outside their own scope. For if that be not provided for, we may be in danger of making the confusion worse rather than better, and adding to a university that does not teach a second that cannot examine.

I have detained you too long and hasten to conclude. It seems strange, indeed, that a profession like ours (which in respect of producing names has no parallel for fecundity) should be baffled by a question which is mainly nominal. Let us take courage from what we have, and be circumspect in our search for more. The joint diploma of the two greatest medical corporations of Great Britain, name it as you will, must have its own value, and may be trusted to stand alone for a little while without meretricious adornment. As for the degree that is one day to supplement it, it will not come the quicker for our present disputes, or the sanguine expectations of those who assert that it is already at the door. With or without our help, a teaching, that is a real London University is at hand, and, as I firmly believe, our own interests lie not in opposition, but in cordial co-operation with those who are now labouring to promote it. Whatever the issue, and with all our differences, there is but one purpose inspiring us—the progress and the honour of a great profession.

One word in conclusion, which shall be addressed to those new comers to whom the details that have occupied us may seem wearisome, and who thought to hear some higher discourse. But, in fact, these matters concern you nearly. For when, according to the common lot, you come to appear at the examination tables of your country, the questions which now vex us will have reached some wise and definite settlement. "The mills of the Lord grind slow; but they grind exceeding small." Your time of preparation will be also the time when the tests to be applied are being made fair, equal, and sufficient; and your examination reward will be of that form which is finally decided to be the best.

Introductory Lecture

DELIVERED AT

ST. MARY'S HOSPITAL

At the Opening of the Winter Session, 1887-88,

BY ANDERSON CRITCHETT, M.A. CANTAB.,

OPHTHALMIC SURGEON TO, AND LECTURER ON OPHTHALMIC SURGERY AT, ST. MARY'S HOSPITAL.

GENTLEMEN,—Had Dante written in the nineteenth century, his magic pen might have done justice to the sufferings of those unfortunate members of our profession who, possibly by way of atonement for errors in diagnosis and faults in treatment, are condemned to pass their short vacation in a vain endeavour to infuse some interest and originality into an introductory lecture. I readily acknowledge, however, that for my own poor part, although for some weeks past I have languished under this cloud of work, it has not been without a silver lining, for I am enabled on my own behalf and on that of my colleagues to offer a cordial and hearty welcome at the opening of our winter session alike to those who have already borne with us the heat and burden of the day and to the new recruits who now join our ranks for the first time. I know that I rightly interpret the feelings of the staff when I express an earnest hope that you will always regard us as your sincere friends, for, believe me, we are actuated by a single desire to promote your welfare and happiness. In return we ask, and I believe we shall not ask in vain, for your confidence and your co-operation. There must be none of the innate distrust with which a pupil too often regards his pedagogue, for we are here *all* students, and though some of us have been pursuing the steep path of knowledge for more years than we care to remember, we all have the same goal in view, we are all striving to compass the same end—the relief of human suffering.

It seems hard that those gentlemen who appear amongst us for the first time should at once be lectured, for as yet they have done nothing to deserve such an infliction, and I feel somewhat in the same position as the stern parent who invariably gave his children a sound thrashing before breakfast on the ground that they might possibly need it later on in the day when he would not be there to administer the correction. I cannot, however, too strongly impress upon you the wisdom of adopting a methodical mode of work. Doubtless "distance lends enchantment to the view" as far as the College examinations are concerned, but that student alone can regard their approach with confidence and equanimity who begins to work steadily and with method from the commencement of his career.

Anatomy and physiology should at first occupy your

Digitized by Google

almost exclusive attention, and your knowledge of these subjects must be sound and practical. Begin by studying the skeleton thoroughly, and be constantly in the dissecting room. Here I would offer a word of advice which may perhaps surprise you—it is this: do not occupy too much time in making elaborate and ornamental dissections. It is, of course, essential that you should acquire manual dexterity and neatness, but I am convinced that the most reliable anatomists are those who relentlessly pursue each muscle and nerve, and investigate each hidden bony cavity, as opposed to others who hesitate to be thorough because they might spoil the appearance of their dissections.

I may, perhaps, shock the feelings of our officers of health by advising you to live as much as possible in an anatomical atmosphere; but I mean by this expression that you should so far allow anatomy and physiology to absorb your attention that they may almost enter into the pores of your skin, and that they should form the chief subject of discussion with your fellow-students, for whose delectation and instruction you should at all times be ready to produce some hidden treasure, such as a carpus or a special cervical vertebra. In the evening you should, by study, not only consolidate the practical knowledge which has been gained during the day, but anticipate the work which lies before you on the morrow, so that, scalpel in hand, you may know what to look for, and where the object of your search is to be found. To those happy beings who have successfully passed the dread ordeal of the first examination, I would offer a few words of friendly warning—"Labuntur anni." In less than three years you must have put on such an armour of knowledge and experience as will enable you to face those terrible opponents—disease and death. Within the walls of hospitals you can witness the daily conflict, and even there, where the weapons of modern science and treatment are wielded by experienced hands, the foe too often gains the victory. But the time is coming when you must each of you and *alone* commence the struggle. The time is coming when the life of a fellow-creature will, humanly speaking, be given into your hands, as

> "When that voice, in feeble moans of sickness and of pain,
> But mocks the anxious ear that strives to catch its sound in vain;"

when the firstborn is in danger, and the mother's eye is turned to you appealingly for help; when the life-blood is flowing fast from the wounded artery, and all depends on your knowledge, precision, and resource. What will be your feelings if at such times you are found wanting because the bitter memory of your student's life shows nothing but a barren record of ill-spent time and wasted opportunities? I cannot, I will not believe that any of those whom I am now addressing will be found in the ranks of the ignorant and the unready. You would prove false to the standard of St. Mary's and its noble past; for as the soldier looks with pride upon the banner that bears the scroll of bygone victories, so we in our turn cherish the names of Alderson, Sibson, White Cooper, Wiltshire, and Meadows—of men who, though their sun has set, still light our pathway with a lingering after-glow of golden memories.

I would once more impress on you the importance of dividing your time into regular intervals of work; but I should also be amongst the first to acknowledge that he will labour most successfully who is ready in due course to relax his mental strings, and promote his physical welfare by healthy and manly recreation. My ideal of a model worker was realised in an old college friend at Cambridge who rowed in the first boat, was the best bowler in our eleven, and came out high enough, amongst the Wranglers, to obtain his Fellowship. You must, I know, accomplish a considerable amount of reading, and become during the long winter evenings slaves of the lamp, but your favourite fields of study should be in the wards, and in the out-patient rooms. There, and there alone, can you gain a sound practical knowledge of medicine and surgery, and I may perhaps be pardoned for the suggestion that you might do worse than devote the scraps of your spare time to the special departments. Later on in your student's career you will become dressers, clinical clerks, and finally, if you are found worthy of high office, house surgeons. In these several posts you will taste the sweets and bitters which pertain to personal responsibility, and I would venture to make a special appeal to you concerning your treatment of the patients who may be placed under your care.

There is a vague impression on the minds of many of the general public that constant familiarity with scenes of suffering begets a callous feeling in members of our profession. I cannot for a moment allow that such is the case; but I earnestly hope you will one and all remember that the accusation of needless cruelty is occasionally, though quite unjustifiably, hurled against us, both in poetry and prose, and it is by deeds, not by words, that we must refute the charge. The divine injunction that we shall "Do unto others as we would they should do unto us" can never be more perfectly carried out than in our treatment of our patients; while the helplessness, and too often hopelessness, of suffering and disease should stir the better feelings of our nature, and stifle harshness with their mute appeal. We should endeavour to combine with a gentle bearing calm judgment and unfaltering decision where prompt action is necessary; there should be the iron gauntlet in the velvet glove. Special care is needed in our treatment of children. A child's confidence is easily won, and a few moments devoted to the accomplishment of that end will not be wasted. Nothing is more touching than a child's implicit faith in our efforts for its relief, or more complete than its gratitude for results achieved.

And now for a few words of counsel as to the best method of utilising the first few years after you have emerged from the condition of student to that of qualified practitioner. There may, of course, be special reasons why some of you must plunge at once into the vortex of practical work; and it is a natural, and I may add a healthy, impulse which makes a young man desire to transfer the burden of expense and responsibility from other shoulders to his own. But I would earnestly advise such of you as have time and opportunity for additional study to pass some of the higher examinations, and, if possible, to acquire a university degree. Believe me, you should thus utilise those few invaluable years when the seed of knowledge is received and germinates in a pure mental soil, and when youthful energy and confidence are as yet unchecked by the cares and responsibilities which must inevitably accompany advancing age. Use, therefore, this priceless time.

> "It will not last for ever,
> Still ebbing from our gaze;
> The waves of life will never
> Bring back those golden days."

I strongly advise you to apply for resident appointments either here at St. Mary's, where, I am glad to say, they are freely open to our students; or, if there be not room for you at home (for with the best desire to do so, we cannot provide in that direction for all our *alumni*), then you must seek "fresh fields and pastures new," at some of our excellent provincial hospitals, where you will find physicians and surgeons from whom you may acquire much valuable knowledge, for the country contains many men who are more than able to hold their own with their metropolitan brethren. After devoting some time in the manner I have indicated, the most serious work of your life will commence. You will now realise more fully that life is real, earnest, and laborious. You will feel that your frail bark has at length quitted its safe anchorage and must sail on unknown seas, where there may be under-currents of jealousy, quicksands of professional rivalry, and sunken rocks of unforeseen disaster and discredit. In spite of prejudice and competition, you must slowly but surely win your way into that hardly-won fortress—the confidence of the public. The struggle will be severe, but let the work be loyally done. Let there be nothing mean or underhand, no attempt to gain credit at the expense of another practitioner, no trafficking with cant or hypocrisy: better to accept an honourable failure than stoop to such miserable expedients, which can but result in complete mental and moral degradation. Remember that material prosperity and wealth are only to be valued as they minister to refinement, to moral and intellectual progress, to the promotion of science, and to the furtherance of that broad and holy charity which elevates mankind. You must be ready to offer upon the altar of public duty that most precious and sacred of all virtues—self-sacrifice. A far abler pen than mine, and one which I may be pardoned for regarding with filial veneration, has thus described the life that is before you:—

"Picture to yourself for a brief moment the life of a medical man in the full tide of his professional career; what a stormy, anxious unrest it is; what exorbitant exactions are made upon his resources; what exaggerated expectations are formed of his powers; what unthinking demands are made upon his vital energies. By day and by night, for rich and for poor, with or without recompense, he must obey the summons of suffering humanity. How many

Digitized by Google

anxious complicated unfortunate cases he meets—cases where great confidence is placed, where great interests are at stake, where the feelings are strongly enlisted—cases where life may be just quivering in the balance, and one slight error of judgment may snap the slender thread; when every eye is turned in anxious trusting faith and eager hope upon him, and he must sustain their drooping hopes by a fictitious calmness and assume a confidence that his judgment belies, until his over-taxed mind and over-wrought feelings are wellnigh exhausted with the effort. Again, he must be ever ready to encounter accidents, disease, and death in all their most appalling forms; when friends are paralysed with fear, and when contagion carries panic to the stoutest hearts, he must be there calm and unmoved. The blanched mother may be fluttering out her own life at the moment when she has given birth to another, the victims of cholera may present all the hideous features of death whilst yet writhing in vital agony, delirium and tetanus may compress the energies of a life in a few brief racking fatal hours, and still he must be there to gaze on sufferings he cannot relieve, and to feel that science is impotent and humbled in the presence of indomitable death."

Such is the picture painted by one who was himself a member of our profession, and who knew the hardships and anxieties of our toilsome life. Are there any now listening to me who hesitate to enter upon the thorny path that lies before them? I have been told that in the Latin Church each candidate for holy orders is required to pass many days in solemn prayer and solitude before presenting himself for ordination. When at length the fateful day has arrived, and they appear before God's altar, the bishop, after pointing out the nature of the sacrifice which must be made in the complete surrender of personal will, of wealth, and of the many attractions of the world, makes a lengthy pause, during which any who may still doubt the depth and sincerity of their convictions may at the last moment reconsider their position, and retire ere it be too late. In like manner, I would not have you enter lightly or unwarned upon the arduous duties and responsibilities which can never be dissociated from our career. Remember that, as in the case of the priest, the sacrifice must be complete and thorough, and that you must give the whole man for the whole time.

Although we feel a justifiable pride in our hospital, in our growing school, and in the number and character of the recruits who now flock around our banner, we would not willingly enlist one soldier of medicine who will not be true to his colours, or who will falter in the presence of the enemy, for we must present a serried and unflinching phalanx, firmly united by the bonds of mutual confidence and by the knowledge that those who fall will not have died in vain. But before you make your final decision, let me turn to the brighter and more sunny side of the medical landscape. "The old order changeth, yielding place to new," and the onward march of time has brought with it so many beneficial innovations in our method of work, and has made such large additions to our instruments of precision, that we go forth to the fray more fully equipped than were our forefathers; indeed, the advance in medicine and surgery has been proportionately rapid as the importance of physiology and pathology came to be recognised, and the phenomenal growth of these two giants has been of comparatively recent date. The early history of our profession is surrounded by an atmosphere of mist and haze, which not unfrequently accompanies the dawn alike of day and of scientific truth, and our brethren in the middle ages seem to have thought that a cloak of mysticism and necromancy would suffice to cover a multitude of medical sins. According to the chroniclers of the time, a visit to the doctor's cavernous sanctum must have demanded a mixture of courage and confidence to which many modern patients cannot lay claim. The dim light of a taper served to throw the contents of the chamber into unpleasant relief. A large stuffed lizard, apparently an indispensable companion, was suspended from the ceiling, while the walls were artistically decorated with toads, snakes, newts, and other slimy creatures; a large crucible occupied a prominent position, and the sulphurous odours which pervaded the room unpleasantly suggested the possibility of the doctor's having entered into an illicit partnership with the gentleman who lured Faustus to his ruin. We are not told whether as much importance was at that time attached to the possession of a good professional manner as is now the case, but the doctor evidently relied not a little upon the impression which a flowing robe, liberally garnished with cabalistic signs, would create upon the mind of his patient, and he was always ready to call astrology to his aid if he found himself face to face with any unusually tough matter for diagnosis. The remedies used in those days appear to have been extremely powerful, and, if history may be trusted, the drugs that obtained the greatest popularity were strong and reliable poisons, which were by no means devoted by the purchasers to the salvation of human life. The treatment of wounds did not err on the negative side, for the immediate application of boiling oil was considered an infallible specific until the practice received a salutary shock after one of the sanguinary battles. The stock of oil was unequal to the demand for it, and the unhappy surgeon, having no better substitute, treated a portion of his cases with cold water, and was much surprised to find that his new and involuntary remedy left the old one completely in the shade. Simplicity is not the least amongst the virtues. A few more revolutions of the wheel of time bring us to the period of the Barber Surgeons, the sign of whose calling showed that their fame for bleeding spread from pole to pole. Then in the sixteenth century came that pioneer of scientific research, the immortal Harvey, and we are proud in the knowledge that St. Mary's men are numbered amongst the most loyal and constant supporters of the Society which bears his name. Time would fail me were I to mention all those who have left the stamp of their genius upon the seal of their time, but the memory of such men as Sydenham, Cheselden, Jenner, and John Hunter makes us recognise with grateful admiration that "there were giants in those days."

And now we come within measurable distance of our own time, and are able to draw our records from living men. Wonderful indeed are the stories we hear of the capacity for disposing of heavy meals and unlimited port which English stomachs possessed at the commencement of this century, and equally wonderful were the heroic means adopted by our professional brethren to remedy the results of gastronomic indiscretion. Periodic bleeding and cupping, with the administration of strong purgatives, were deemed matter of necessity, and there was a constant supply of that which Ingoldsby has well described as

> "That nasty green fluid they so often send us
> Labelled, 'Haustus cartharticus mane sumendus.'"

It must have been as a mild protest against this system that a patient, when asked by the doctor whether he had followed his prescription, replied, "Certainly not; if I had I should have broken my neck, for I threw it out of the window." It was a matter of certainty that there would be a reaction from such a system, and the recoil took us so far in the opposite direction that I am amongst those who think with our respected friend, Dr. Hare, that we sometimes fail to take advantage of old and valuable remedies because their indiscriminate employment has brought them into deserved discredit.

Now let me turn from the period where I must rely upon the memory of others to that which comes within the circle of my own experience. In how many directions the sappers and miners have been successfully striving to compass the overthrow of suffering and disease, and in regions which had previously been deemed impregnable. I have only to allude to the extraordinary advances made in abdominal surgery, and in the treatment of stone both in the kidney and bladder, and to the brilliant results of ovariotomy with which the honoured name of Sir Spencer Wells must ever be associated, to prove the truth of my assertion. Then, again, even the opponents of Sir Joseph Lister must allow that the introduction of his system has taught us the incalculable advantages which accrue from extreme care, cleanliness, and attention to sanitary laws. The progress in medicine may not have altogether kept pace with the recent rapid strides made in the field of surgery, but the advance has nevertheless been sure and steady, especially in our knowledge of the pathology and treatment of diseases of the nervous system; while the comparatively new discoveries in bacteriology open out an almost illimitable area for researches, and may, I trust, lead to the downfall of many of those terrible diseases which have hitherto baffled their pursuers. We are proud to know that British physicians and surgeons can claim a sufficient share in the advance of science, but we must readily and gratefully acknowledge the heroic self-sacrificing and successful labours of our professional brethren both on the Continent and in America.

And now, before I conclude, I trust that my friendly

Digitized by Google

audience will pardon me if I stray for a few moments into those Elysian ophthalmic fields where I have passed my happiest days, and which, though small in area by comparison with the vast tracts of surgery and medicine, possess a soil that yields some of the sweetest flowers of human gratitude.

I am old enough to remember the introduction of the ophthalmoscope by that great teacher and thinker, Helmholtz, who, I rejoice to say, yet lives to witness the priceless boon which his discovery has conferred upon the human race. It is difficult for those who are now familiar with its use—and their name, I trust, is legion—to conceive the wondering eagerness with which the original workers sought by the aid of their new weapon to bring to light those numerous hidden diseases of the eye which had till then been only partially and most imperfectly recognised. Many modifications of the instrument have since been introduced, and amongst the most recent and most useful improvements has been the ingenious adaptation of the electric light to the ophthalmoscope by my colleague, Mr. Juler.

Then, again, I remember the introduction of the subconjunctival operation for strabismus with hook and scissors, and the present method of enucleation of the globe, and with each of these operations the name of my honoured father must be associated. In the latter case the improvement on the previous rough and almost brutal method was so marked that the new plan was freely practised, and as there was a rather large stock in hand of eyes which needed removal, our witty friend and colleague, Monsieur Warlomont of Brussels, had perhaps at that time some slight justification for his suggestion that unless an oculist had enucleated at least one eye during the day he could not sleep well at night. About this period the venerated Nestor of English ophthalmic surgery, Sir William Bowman, inaugurated a new mode of dealing with epiphora and obstruction of the lacrymal duct by slitting the canaliculus and passing probes of various sizes; and he has been followed by Weber, Stilling, and other intelligent workers, who have grafted many ingenious additions to the parent stem. In 1856 came the remarkable discovery by our beloved von Graefe that the dread disease glaucoma, which had till then defied all the efforts of ophthalmic surgeons, might be successfully subdued in the greater number of cases by that safe and simple operation, iridectomy. He met the usual fate of great inventors, and encountered in many directions an opposition which was doubtless honest, but by no means unprejudiced; and I cannot but remember with pride that he received most loyal, and, as he gratefully owned, most valuable support from Sir William Bowman and my father, and from the large majority of English ophthalmic surgeons. The fact that iridectomy was too readily assumed to be a universal remedy, and that the iris seemed to act upon the minds of some oculists in the same manner that a red rag does upon a bull, by no means detracts from the merit of von Graefe's brilliant discovery. It has stood the severe test of the experience of thirty years, during which time it has been exposed to the searching rays of professional opinion, and its merits and demerits have been repeatedly and exhaustively canvassed; and although its efficiency in certain forms of chronic glaucoma is doubted by some, all must now admit that it is of inestimable value in the acute and subacute conditions of the disease. To von Graefe also belongs the credit of having introduced an operation for extraction of cataract, which, with certain slight modifications, remains to this hour the most successful and the most generally adopted method.

To our countryman, Mr. Jonathan Hutchinson, we are indebted for the discovery that certain forms of eye disease may be directly traced to hereditary causes.

We must not forget that amongst the numerous improvements in our art which have come from our distinguished confrère, Dr. De Wecker, of Paris, we have sclerotomy, the handmaid of iridectomy, being sometimes used as its efficient substitute, and sometimes as its successful supplement. From him also comes the treatment by jequirity in cases of pannus, and the application of the tattoo to dense and disfiguring leucomata. I can but glance briefly at the great progress made in the introduction of peritomy, of inoculation, of improved plastic operations on the eyelids, of evisceration, and of the methods of dealing with conical cornea; but I must not omit to make grateful allusion to that valuable local anæsthetic, cocaine, which, though a boon to all humanity, renders such exceptional service to the ophthalmic surgeon.

At the risk of taxing your patience unduly by dwelling too long upon this special subject, I must remind you of the colossal work achieved by the illustrious Professor Donders, who has opened out a new world for thought and investigation, and has elevated the study of practical optics to the dignity of a science. He has taught us that strabismus, headache, some forms of diplopia, ciliary spasm, and many other evils frequently depend upon some uncorrected error of refraction, and by placing it in our power to give the required relief, he has proved himself one of the greatest benefactors to humanity which the century has known.

You will acknowledge that the record of the last forty years is one upon which the ophthalmic surgeon can look back with mingled feelings of pride and thankfulness; but much remains yet to be done, and I trust that the time is not far distant when the spread of knowledge amongst us will alter those terrible statistics of sight lost in infancy through ignorant or wilful neglect of necessary care and treatment, and will also arouse the instructors of our children to a sense of their duties, and induce them to make that essential provision of light which is now too frequently absent.

You will, I am sure, desire that I should express the great regret which we all feel in losing the valued services of Sir Edward Sieveking, who joined St. Mary's Hospital when it began its struggle for existence, and has remained to see the fertile fruition of his labours. I must also, on your behalf and on my own, allude with grateful pride to the good work which has been accomplished, both for hospital and school, by our Dean, Mr. Field.

For the rest, gentlemen, I would entreat you to be ever mindful of the dignity of your calling. Regard not that calling from a commercial point of view, but rather from the high standpoint of philanthropic science. In manly emulation you may well engage—it is the soul of scientific as of all other enterprise; but, oh, beware those jealous feuds and petty rivalries which degrade a glorious contest to the level of a mean and merely personal competition. Let no sordid, selfish aims ever tempt you into courses derogatory to the true motive and purpose of your pursuits—the alleviation of human suffering. Never forget the saying of a famous surgeon, "Ours is the noblest of professions, but the vilest of trades." A due sense of the honour of your art will make you nicely observant of your own. Nor will you fail to remember that, even in the case of the most gifted student, industry is the indispensable handmaid of success. The mental, as the material, soil needs for the yielding of an abundant harvest careful culture, only to be achieved by thorough hard work and anxious observation. "Pater ipse colendi haud facilem esse viam voluit."

It is given to few members of our profession to achieve undying fame. The artist leaves the record of his genius on the painted canvas, and wondering ages worship at his shrine; the poet lives again in words of song that hang upon the lips of countless generations; and the musician breathes his soul into the enchanting melodies that echo for all time. Such fame is not for you. Yours is the priceless luxury of doing good; and in the gratitude of those whose pains you mitigate, whose sorrows you assuage, there lies a richer and a nobler recompense than "proudest record 'mid the tombs of kings." Be therefore of good heart. Rest assured that the reward which waits on diligence will in the fulness of time fall to your lot. As Hamlet says, "If it be not now, yet it will come: the readiness is all."

THE VALUE OF SHORTHAND TO THE STUDENT AND TO THE PRACTITIONER OF MEDICINE.[1]

BY W. R. GOWERS, M.D., F.R.S.

AMONG the miscellaneous uses of shorthand, not the least important is its value to the student of every kind. First to the student who learns by listening to oral lectures. Many students take notes of lectures in longhand. The process, however, interferes much with the thorough comprehension of the lecture, and so some students prefer simply to listen, to "take in" all they can, and trust to "reading up" the subject afterwards in books, to supplement their recol-

[1] Read before the International Shorthand Congress.

Digitized by Google

lection and to learn the details that they fail to remember. Shorthand enables the student to secure the necessary abstract in writing, and at the same time to give almost as much attention to the subject as if he took no notes. But for this he must have a thorough mastery over the art. The temptation to the student who writes shorthand is to take down too much. A *verbatim* or really full report of a single lecture will occupy the whole of the evening in its revision and correction, even if it is not written out; and most students have to hear and master three or four lectures a day. To take a full report is a mistake; a good and terse abstract is what is needed, and, as I say, this can be taken in shorthand without any interference with the needful attention to the subject-matter; nay, the making of the abstract deepens the impression made by the speaker's words, and the student is actually able to carry away in his mind more of the lecture than if he merely listened to it or made an abstract in longhand. Longhand notes, like a leaden weight, keep the student constantly behind the lecturer, so that he has from time to time to omit in order to catch the speaker up. But the whole value of shorthand depends on the efficiency with which it is written. If the student has to attend to his writing, he cannot attend to the lecture. Hence the oft-repeated lesson that shorthand should be taught, and taught thoroughly, at school, so that the student starts in his pursuit of knowledge well equipped with this most useful weapon. If he has not learned it at school, it will still be well worth while for him to devote the needful time at the outset of his studies. He need not seek to acquire a very rapid speed, but he should be able to write 100 words per minute with the perfect ease of almost automatic action. An hour a day for three months will, in most cases, suffice to give the needful dexterity.

Shorthand is most useful to the student of what are called Arts and Literature. The facility which it gives of making brief abstracts of important facts and opinions is extremely valuable. My own old Latin and Greek text-books are studded with shorthand notes—notes of translation, on grammatical construction, on geography and history. But its value to the student of science is still greater. The well-known maxim of Captain Cuttle should be the motto of every student and investigator, and he who can write shorthand will, as a matter of fact, secure twice as many notes, and notes that are twice as useful, as he who does not write shorthand. "There is not time to make a note of it," is always hampering the longhand writer, but to the writer of shorthand the very meaning of the word "time" is almost changed. Minutes acquire the value that hours have to others.

To the student of medicine these remarks apply with peculiar force. Besides the set lectures that he has to attend, much of his teaching is at the bedside of the patient, or in the room in which out-patients are seen, and of the facts that come under his notice, and the lessons he receives, two-thirds at least are lost unless shorthand enables him to secure them. When he ceases to be a nominal student—for he should never really cease to be one—its value still continues, for in nothing is its advantage more strongly felt than in the process of taking notes of the cases of disease that come under his observation and care; notes which are often necessary, not only for his sake, but for the sake of the patient. Whilst the patient is describing his symptoms, they can be taken down in as full detail as is needful, and all the results of the examination can be recorded in a few minutes. I speak from experience, grateful experience, for I possess shorthand notes taken by myself of not less than twenty thousand cases of disease; of one kind of disease alone I have notes of nearly five thousand cases; and I am sure that the notes would not have been half as numerous, and not more than one-third as useful, had they been taken in longhand. And yet, strange to say, in no profession is shorthand less used, and I have observed with much surprise that I am the only member of the medical profession taking part in this Congress. In scientific work in medicine it is the same story. The facility the art gives in abstracting the work of others (I do not mean stealing), in collating facts, in arranging materials, in preliminary composition, in all but preparation for the press, its value is felt at every turn by those who possess the art. But for all this, shorthand must be well known; the worker must be able to write without thought and to read without effort, and the time spared from other work to acquire the needful dexterity will ultimately be repaid a hundredfold.

[I may anticipate a question that is sure to be asked by some readers of this paper, What system of shorthand is the best for these purposes? There is some difference of opinion as to the system best adapted for very rapid *verbatim* reporting; but there is a general consensus of opinion among shorthand writers of all systems that, for the miscellaneous uses here indicated, Pitman's phonography or phonetic shorthand is the best. Even for rapid writing it stands among the first, and is employed by many of the swiftest living writers. I have written it for nearly thirty years, and can testify to its excellence. Moreover, it has the advantage that there is a very large amount of literature published in it, including the works of many standard authors, several periodicals, and a dictionary of 50,000 words. Thus the facilities for acquiring the necessary ability to read this system are very great.]

SOME CONSIDERATIONS ON THE PATHOGENESIS OF DISEASES IN WOMEN.[1]

BY WILLIAM B. NEFTEL, M.D. NEW YORK.

AT the beginning of my medical career I was in charge of a ward for consumptives (tuberculosis of the lungs) in the large hospital attached to the medical school in St. Petersburg. At that time the absolute incurability of tuberculosis was a firmly established dogma, and any attempt to cure the affection, or even to arrest its progress, would have brought odium upon the investigator; certainly he would have been considered ignorant of scientific medicine, especially of morbid anatomy and pathological histology. Indeed, since the researches of Rokitansky, the progressively destructive character and the constitutional nature of tuberculosis were well known to every educated physician, and against that generalised destructive process it was thought medical science and art must always remain powerless. The utmost that could be done for these unfortunate patients was to alleviate their suffering by narcotics, and to diminish the colliquative excretions, at the same time carefully watching the progress of the disease to its fatal termination. The greatest care and study were devoted to the physical examination of these patients, and the diagnostic details had to be verified or corrected at the inevitable necropsy. It is true that at the post-mortem sometimes a characteristic cicatrix would be found in the lungs, thus indicating the healing of a former cavity, or, what was still more suggestive, such cicatrices would be found occasionally in the lungs of persons who died of other diseases, and in whom therefore a spontaneous cure of tuberculosis had undoubtedly taken place at some previous period of life. But such cases were considered simply as exceptions to the rule. And yet the truly scientific physician knows that there can be no exception in nature, and if there exists only one case of cure of tuberculosis, a similar result can be obtained in any given number of such cases, provided all the conditions are known under which the so-called exceptional case got well.

Entirely under the influence of the prevailing notions with regard to the incurability of tuberculosis, I met a case in private practice which by its peculiarity seemed to throw some light upon the etiology of this disease. In a large family, all the members of which were remarkably strong and healthy, and in which tuberculosis had never existed for generations, one married daughter, twenty-nine years old and mother of two children, was affected with pulmonary consumption. This patient was endowed apparently with the same robust constitution, and even the same features, as the rest of the family; she was brought up in the same locality and under the same healthy sanitary conditions, and yet was the only member of the large family affected with tuberculosis of the lungs. Her disease was diagnosed by competent physicians, and the diagnosis corroborated a few years later at her death.

This patient was for a time under my observation, and gave a detailed account of her previous history, and even explained the cause to which she attributed the origin of her disease. When a girl she was remarkable for robust health. During several years, while living in a fashionable

[1] Read in the Section of Medicine of the International Medical Congress, held at Washington.

Digitized by Google

boarding-school, she wore day and night a tightly-laced corset in order to have a small waist, and was admired for her beautiful figure. She continued to wear her corset, even while asleep, after having left school, and gave it up only after marriage. Even whilst at school she became pale, and was often troubled with a dry, hacking cough, which, after marriage, became more troublesome, and at times was accompanied by febrile movements and increased expectoration. After the birth of her first child the symptoms of pulmonary consumption became manifest. The disease progressed slowly, and at the age of thirty-three the patient died in an advanced stage of general emaciation.

This case, by the simplicity of the conditions under which the disease originated and developed, could be compared to the exactness of a pathological experiment on animals. Indeed, the patient was in perfect health, and without any predisposition to tuberculosis, like all the other members of her family, but became tuberculous after a special condition had been introduced—a condition entirely absent in the others—viz., tight lacing. The positive result of this experiment appeared to me at the time a complete demonstration of the fact that a steady methodical compression of the chest and of the upper portion of the abdomen, continued for a certain length of time, can produce tuberculosis in a perfectly healthy person without hereditary predisposition to the affection. Of course there was no difficulty to find a hypothetical explanation of the fact in accordance with the prevailing theoretical ideas. The compression interfered with the free circulation of blood in the lungs, producing stasis, chronic inflammation, and exudation. The latter, according to the existing blood crasis, could become either organised, or else transformed into pus, tubercles, &c. I was determined to test this hypothesis by experimenting on animals, when working in Virchow's Pathological Institute in 1860. I will give here only a few examples taken at random from my old notes, as all the other experiments present almost identical results.

Experiment 2.—May 22nd: I applied a bandage, producing moderate pressure, around the chest and abdomen of a well-nourished black rabbit.—23rd: The rabbit manifested a high degree of dyspnœa, and the conjunctivæ were congested and the urinary secretion exceedingly scanty.—24th and 25th: The symptoms increased in severity, respiration very frequent and superficial, and conjunctivæ dark-red, forming a thick chemotic wall around the cornea.—26th: The animal was found dead. At the necropsy the internal organs, especially those of the abdomen, presented an intense venous congestion, there was dilatation of the right heart, and arterial anæmia of all the parenchymatous organs.

Experiment 3.—On May 29th a bandage with very slight pressure was applied around the chest and abdomen of a well-nourished white rabbit. The symptoms of dyspnœa, &c., developed more slowly, but in a few days reached the same climax as in the preceding experiment, and on June 11th the rabbit was found dead, with the post-mortem appearances as in Experiment 2.

Experiment 11.—June 12th: A bandage producing considerable pressure was tied around a large rabbit.—13th: The animal breathed with great difficulty and the bandage was taken off.—14th. Bandage reapplied quite loosely.—23rd. The rabbit appeared much emaciated, though the morbid symptoms were not acute, and on the 29th was found dead. At the necropsy there was considerable emaciation of the whole body, with arterial anæmia, dilatation of veins and of right heart; in the lungs nothing unusual.

The fatal result was uniform in all the rabbits experimented upon, even when the bandage of the chest and anterior portion of abdomen produced but a slight pressure. I then tried to entirely exclude pressure, and applied the bandage very loosely. Under this modification the acute symptoms would not appear, and some of the animals lived to the end of the session (August), when they were killed mostly by Claude Bernard's piqure; in some, however, death occurred spontaneously. In all of them the necropsy showed arterial anæmia and venous stasis with dilatation of the veins and of the right heart. Especially the liver was always greatly congested and enlarged, but nothing of special interest could be discovered in the lungs. Only once a generalised pathological process was found, closely resembling, if not identical with, tuberculosis. I tried the same experimental method on dogs in Berlin, and continued it in Dr. Harley's laboratory, University College, London, but with a still less satisfactory result. It was almost impossible to keep the bandage in position on dogs, unless made of plaster-of-Paris, and even then the animals would gradually succeed in loosening it to such an extent that a positive effect could not be obtained.

Experiment 8.—May 30th: A plaster-of-Paris bandage was applied rather loosely around the chest and anterior portion of the abdomen of a dog. The animal manifested no morbid symptoms.—June 14th: The bandage became perfectly loose, and had to be reapplied.—July 4th: The dog was found dead. At the necropsy a rather moderate degree of arterial anæmia and venous stasis in the internal organs existed. At the lower end of the spleen was a small infarction of the size of a pea. The small intestines were spasmodically contracted. As this was the only case of spontaneous death in a dog after the application of a bandage, I suspected accidental poisoning in the laboratory.

All the other dogs were killed in various ways at the end of the session, the necropsy showing in those where the bandage was efficiently applied general anæmia and dilatation of the right heart, with venous congestion of the parenchymatous organs, but in no case was there any special affection of the lungs. I finally abandoned these experiments, partly because they did not corroborate my original expectation to produce tuberculosis by compressing the chest, but more especially in consequence of Villemin's researches,[2] which proved that tuberculosis could always be produced by inoculation with tuberculosis. Villemin's views met with much scepticism at the time, but at present they appear quite prophetic. For instance, the contagiousness and specific nature of the organic poison of tuberculosis multiplying itself in the system, &c. Villemin thus diverted the entire question into a totally different direction, which ultimately led to the discovery of the bacillus tuberculosis.

On account of the negative result of my experiments with regard to the etiology of tuberculosis, I have not published them, although they offer some positive results in other respects. They demonstrate the deleterious effects of a continuous compression of the chest and abdomen in animals, even when applied in a moderate degree. It produces general arterial anæmia and venous stasis in the parenchymatous organs, especially in the liver and other abdominal organs. As regards the question of tuberculosis, the important result obtained by Villemin was soon threatened to be entirely lost by the subsequent work of numerous investigators who with faulty unscientific methods apparently succeeded in proving that tuberculosis can be produced by inoculation not only with tubercular substance, but with almost any substance, organic or inorganic. Fortunately, the admirable researches of Cohnheim's first experiments, conducted with Fraenkel, which, owing to imperfect methods, had led to the erroneous assumption that tuberculosis was produced by the absorption of inspissated pus, and were later refuted by himself, proved conclusively that tuberculosis is a specific infectious disease caused by a distinct living micro-organism present only in genuine tubercular substances; but its actual demonstration was left to Robert Koch. The brilliant researches of the latter show beyond any possibility of doubt that the bacillus tuberculosis is the real and only cause of tuberculosis, that without it tuberculosis is impossible, and that inoculation with the pure culture of the bacillus always produces tuberculosis. The effect of Koch's discovery on the profession was overwhelming. Not only the diagnosis of the disease became always positive and easy, but it was generally expected that with the knowledge of the etiology of the disease the prophylaxis and the treatment of tuberculosis would become successful. In this respect, unfortunately, the general expectation has not yet been realised, and matters remain exactly as they were before Koch's discovery; now, as before, the fifth part of the population die from tuberculosis. Moreover, although the bacillus tuberculosis is omnipresent, and hence everyone is equally exposed to the infection, yet only certain persons of predilection, those with a so-called phthisical *habitus*, or under certain conditions, are liable to become affected with pulmonary consumption. In other words, besides the bacillus a certain predisposition on the part of an individual is requisite in order to become consumptive. Thus we are practically brought back to the same condition of things which existed previously to the disease of the bacillus, inasmuch as the primary factor in the production of the disease is the predisposition. So far we are able to form hypothetical

[2] Cause et Nature de la Tuberculose, &c. Comptes Rendus, lxi., 1866. Gazette Hebdom., Nos. 48, 49.

Digitized by Google

suppositions as to the nature of this predisposition to phthisis. For instance, a person may be considered predisposed when the respiratory mucous membrane is in a state of chronic irritation, and both the local and general resistance are diminished. The interesting researches of Metschnikoff[3] and his phagocytic doctrine, lend experimental weight and evidence to this hypothesis.

Again, the so-called phthisical *habitus*, a peculiar faulty formation of the chest, with weak respiratory muscles and general debility, is justly considered a predisposing cause of pulmonary consumption. Under these circumstances, the lungs not being thoroughly ventilated, the stagnant air and the slow pulmonary circulation afford a favourable condition for the settlement and proliferation of the bacillus tuberculosis. Perhaps the development of tuberculosis in the case above stated could be explained in a similar way. The prolonged compression of the chest by tight lacing in the perfectly healthy person seriously interfered with the normal pulmonary ventilation and circulation, and thus produced the same conditions which are so favourable for the development of consumption in persons with a congenital *habitus phthisicus*. I therefore maintain, though merely as a hypothesis, that compression of the chest by tight lacing, and continued for a certain length of time, constitutes a predisposing cause of pulmonary consumption.

As already mentioned, my experiments on animals show that a prolonged compression of the chest and abdomen invariably produces anæmia and venous congestion of the liver and other abdominal and pelvic viscera. Analogous results are frequently met with in human pathology. I often had the opportunity, especially in Berlin, of being present at the necropsy of women in whom the liver presented the characteristic malformation known as corset liver, and of which some illustrations are given in the classical work of Frerichs on Diseases of the Liver. In accordance with our present state of knowledge, the liver plays an important part in the hæmatopoietic function, and not only in the formation of blood, but also in its destruction. It is evident, therefore, that the distorted shape of the liver produced by tight lacing must necessarily interfere with its normal functions, and also that a continual disturbance and obstruction in the system of the portal vein must act injuriously upon the other abdominal organs. Hence the impairment of blood formation, of circulation, of digestion, and the engorgement of the internal sexual organs, the latter condition being a predisposing cause of obstinate chronic affections of the uterus and ovaries. The so-called corset liver is accompanied by a changed shape of the long framework of the chest, the ribs assuming a wrong direction, in which they become permanently fixed.

For the sake of brevity I will not draw clinical pictures of the morbid conditions induced by tight lacing and improper mode of dressing, for every medical practitioner is acquainted with these daily occurrences. It seems necessary, however, to call the attention of the profession to the following experiments, which have a direct bearing upon the subject under consideration. Schreiber[4] was able to produce experimentally albuminuria in persons whom he subjected to compression of the chest. After moderately compressing the chest in young and perfectly healthy persons, even during a minute and a half only, the urine always contained albumen in quantities varying from a trace to 2 per cent., according to the length of time the compression lasted. The albuminuria continued after the cessation of the pressure from one to thirteen hours, the urine containing occasionally, besides, albumen, hyaline casts, and red and white blood-corpuscles. Schreiber attributed the albuminuria following compression of the chest to stasis in the pulmonary circulation, produced by the diminished respiratory expansion of the lungs, and by diminished negative thoracic pressure. This condition leads secondarily to stasis in the renal bloodvessels, with consecutive alteration of the renal tissues.

There can hardly be a doubt in the mind of the medical profession that women's dress, especially the pressure exercised by it upon the chest and abdomen, must necessarily produce an injurious effect upon their health. Indeed, it would be quite impossible for anyone, unaccustomed from childhood to the female wearing apparel, to bear it for a single day without great discomfort. Only by a constant habit of wearing it a certain tolerance is created, owing merely to the fact that the compression gradually changes the natural shape of the internal organs, and even of its bony framework, just in the same way as the feet of the Chinese women become distorted by methodical compression. The last comparison is by no means exaggerated, and it can be truly said that the deformed feet of the Chinese women do less harm to their owners than the distorted viscera of our women. In view of this grave source of discomfort and disease it is hardly worth mentioning the minor inconveniences of women's dress. Anyone, for instance, who would try to wear several hours daily their high-healed shoes would soon become troubled with backache and general fatigue. I believe a certain kind of headache and facial neuralgia, induced by neuritis, is sometimes caused by exposure of the head, covered only by a fashionable bonnet in a northern winter. That such an uncomfortable mode of dressing unfits women for continuous and often hard work is self-evident. It seems strange that women, even those of great intelligence, do not modify their costume more in accordance with hygienic requirements, comfort, æsthetic taste, and common sense. Female fashions, as we all know, have their headquarters in Paris, where they are invented by a clique of uneducated dressmakers, totally ignorant of hygiene and devoid of æsthetic taste. From this principal centre the fashion instantly spreads to all the European courts and to America, and soon reaches the remotest parts of the civilised female world. All must submit to the dictates of fashion, which is the most absolute of despotisms, and against the decision of which, no matter how absurd and injurious, an appeal is impossible.

That a sanitary question of such magnitude effecting injuriously half of the population of civilised nations, and capable of transmitting morbid tendencies to future generations, is of vital importance and deserves immediate attention, will be admitted by every physician. I believe the only competent authority capable of remedying the existing evil is the International Medical Congress. After having tried in vain to influence the opinion of my own patients, among whom were a number of intelligent lady physicians, in favour of a healthy reform in the way of dressing, I now take the liberty of proposing to the International Medical Congress to appoint a commission to investigate the whole question of dress for women, and to report at the next meeting of the Congress. Such a commission might consist not only of physicians, but also of pedagogues, of artists, and of cultivated ladies from different countries, and would have in view, besides the health and comfort, the æsthetic taste of the sex, of which beauty and modesty are the distinctive characteristics. The work of the commission could begin with an inquiry into the different national costumes, which might offer some practical hints, as their usefulness has already stood the test of centuries. Above all, however, the commission could take into consideration the dress of the classical antiquity, as the idea of simplicity, grace, and comfort, which perhaps would become again a perfect model, when adapted to the changed requirements of modern life and to the various climatic differences. The inauguration of the much-needed reform in the dress of women by the International Medical Congress assembled in America would have a peculiar significance America has already powerfully contributed to the reform in the household affairs of women by the invention and introduction of the sewing, washing, and other machines utensils, and appliances, which have relieved women of so much tedious work, and have saved time now devoted to physical, intellectual, and social culture.

THE MEDICAL ATTENDANCE ORGANISATION Committee will resume its sitting on Tuesday next, when they will consider a circular which they propose sending to the Metropolitan Hospital Committees upon the "desirability of forming a union between the hospitals and provident dispensaries," asking them to appoint representatives to attend a conference on this subject. After this the committee will proceed to consider the scheme which they have prepared "for the medical attendance of the industrial classes in the metropolis." If the proposed conference on the first question can be held in the early part of November, it is hoped that the committee will be ready with a full report in December, when a meeting will be called to consider the whole question.

THE POSSIBILITY OF OPERATIONS ON THE ŒSOPHAGUS THROUGH THE STOMACH AS SHOWN BY DISSECTIONS.[1]

BY MAURICE H. RICHARDSON,
ASSISTANT PROFESSOR OF ANATOMY IN HARVARD UNIVERSITY, SURGEON TO THE MASSACHUSETTS GENERAL HOSPITAL.

A LITTLE more than a year ago my attention was first drawn to this subject by the patient whom I shall have the honour to present here to-day. At the time he came to the Massachusetts General Hospital for relief, his condition was so deplorable, and immediate action was so imperative, that there was no time for any preliminary work upon the cadaver for the purpose of studying the best methods of performing what has proved to be a new operation in surgery. The details of this case have already been published, with some few observations on the operation and the anatomy of the œsophagus.[2] Since that time I have made many dissections for the purpose of showing the best way of doing this operation, and of demonstrating the possibility of reaching any part of the œsophagus with the finger. In all the dissections the distance was measured from the upper incisors to the cardiac orifice, as well as that from the cardiac orifice to the point in the neck where external œsophagotomy is usually performed.

The patient, a man aged thirty-seven, tall and strong, weighing when in health from 160 lb. to 180 lb., had swallowed while eating a denture of four teeth. He had presented himself at the out-patient department of the hospital the next day, and I examined him then. The teeth were lodged near the cardiac end of the œsophagus. He was admitted to the hospital, and numerous attempts were made to dislodge them. At one time sufficient traction was used to break the coin probang which had been made fast to the plate. He was finally discharged from the hospital, having gained in weight, and it was thought that the foreign body had passed into the stomach.

Eleven months after the accident the man came again to the hospital, and the foreign body was found to be in the same place as before, fourteen inches from the upper incisors. The patient was reduced to 113 lb. in weight. He had continual pain, and it was with great difficulty that he was able to swallow enough liquid food to keep him alive. There were two methods of procedure possible, all attempts at removal through the mouth having failed: one by external œsophagotomy, in the manner described by Dr. Leroy Maclean of Troy, and so successfully performed by him;[3] and the other through the abdominal wall and stomach. I selected the latter method because it had been shown that the plate was very firmly impacted indeed, and it was very probable that it would be necessary to use the fingers in dislodging it. For two days before the operation the patient was nourished by enemata, and nothing was taken into the stomach but water and stimulants. After etherisation a cut was made parallel to the lower margin of the ribs on the left side, six inches in length, through which the stomach was drawn and held upon aseptic towels by assistants. A small opening through the stomach wall was next made midway between the curvatures, and forceps introduced for the purpose of grasping the plate. The cardiac opening could not be found. The cut was then enlarged enough to admit the right hand, which was introduced till the œsophageal opening was found. The foreign body was detected by the fingers about two inches above the diaphragm; after considerable careful manipulation with the index and middle fingers the plate was detached and removed. The mucous membrane of the stomach was closed with a continuous silk suture, after the method of Lembert. The patient made a good recovery, though complicated by slight lung symptoms, caused probably by the breaking of a small peri-œsophageal abscess into the lung by the manipulation of the fingers. He rapidly gained in weight from 113 lb. to 167 lb., and went to work as a teamster. He is now perfectly well, and able to do as hard a day's work as any man. In the selection of the above operation and in its first performance various questions arose, to the solution of which I devoted what little time I had. As will be seen, I was ignorant of several important points which I have since demonstrated. I am positive that the foreign body could have been removed with instruments had I known at the time what now I do about the subject.

During the past winter I have operated on sixty patients, and made various observations, the general result of which I herewith submit. The first question that naturally arose was as to the exact location of the foreign body with reference to the cardiac end of the œsophagus, and also with reference to the cricoid cartilage, in order that an intelligent choice might be made between gastrotomy and external œsophagotomy, it being taken for granted that that operation is better in which it is possible to use the fingers if instruments fail. The second question was:—What portion of the œsophagus is accessible to the fingers after the operation of external œsophagotomy, and what after gastrotomy? If gastrotomy is first performed, the best incision through the abdominal wall for reaching the cardiac end with the finger, and the best where instruments are to be introduced? Finally, the best incision through the walls of the stomach, and the details of the operation as to the manipulation of the stomach and œsophagus.

Location of the foreign body (or condition requiring operation).—If it is known how far the obstruction is from the upper incisors when the head is thrown back, in the position for passing the exploring probang, and if the distance from the same point to the cardiac opening is determined, it is evident that we can tell immediately whether the obstruction can be reached from below or not. The results obtained in the measurement of fifty-five subjects show that the distance from the upper incisors to the opening in the diaphragm is not constant. The average distance is fourteen inches and a half (36·8 cm.). Unfortunately there is no constant ratio between the height of the individual and this measurement. One subject six feet in height measured between the points mentioned fourteen inches and a quarter. Another, with a height of four feet ten inches, measured fifteen inches and a half. The greatest distance was seventeen inches, and the least ten and a quarter. The average distance from the cricoid cartilage to the cardiac opening was seven inches and a half in nineteen subjects, taken at random. The greatest distance was nine inches and a quarter, and the least six and a half. From these figures it must be said that it is not possible to locate the foreign body accurately, with reference either to the cardiac opening or the cricoid cartilage. If the individual is of average height, and with a neck of ordinary length, it is safe to say that the distance from the incisors to the diaphragm is about fourteen inches and a half. If the probang is arrested at a point more than thirteen inches from the incisors, the point of obstruction is probably at or near the cardiac end of the œsophagus. Inasmuch as the œsophagus is constricted at the diaphragm, it goes without saying that foreign bodies that have passed the constriction at the upper end are probably at the cardiac end. All parts of the œsophagus are accessible to the finger, either by gastrotomy or by external œsophagotomy.

In all the subjects examined, this fact was observed: In some of them it was quite difficult to reach every part, but it was nevertheless possible. The method of making these observations was to do first an external œsophagotomy in the usual way. Then the stomach was opened and the fingers of the left hand introduced into the cardiac opening. With the forefinger of the right hand in the upper wound and the forefinger and middle finger of the left hand in the lower end of the œsophagus, it was found possible, not only to make the fingers touch, but in many cases to make them overlap quite a distance. Coins and other bodies were passed from one hand to the other in both directions with great ease. In some cases it was necessary to use both the index and middle fingers of the right hand as well as the left.

It cannot be denied that these conditions of observation cannot be reproduced on the living subject, and that the results are therefore only approximate. It would be hardly practicable to do both operations on the same patient. If both hands are in use pushing towards each other it is of course much easier to bring the fingers together and to push the foreign body from one finger to the other waiting to receive it. Yet even in the living I think it is safe to say that there is no point in the œsophagus which cannot be reached by the finger, either from above or below. The other source of error is in the fact that in the cadaver the

diaphragm is relaxed. This does not make any appreciable difference, however, because the opening in the diaphragm is so fixed to the bodies of the vertebræ that it does not share to any extent in the contractions of that muscle. It is possible to reach with the left hand three inches above the cardiac opening—that is to say, the length of the left middle finger. From above, through the wound in the neck, one cannot reach quite so far on account of the sternum and clavicle. One can, however, easily reach the arch of the aorta, and even hook the finger under it in some cases. In a few of the dissections, the measurement was made between the centre of the incision in the neck to the diaphragm. The distance was a little over six inches. Allowing in the average neck an inch and a half to two inches from the cricoid cartilage to the lower point of the incision in the œsophagus, in external œsophagotomy we have the average distance from that incision to the cardiac opening of five and a half to six inches.

The general conclusion to which I have arrived from these measurements and digital explorations is that the obstruction can be reached by the finger in all or nearly all cases when it is situated more than six inches below the cricoid cartilage. If less than six inches below the cricoid ring, it can be reached best from above, though in some few cases it may be just beyond the reach of the finger. Even in these cases instruments can be easily and intelligently applied. The measurements of the point of inspection or obstruction having been carefully made, and it having been demonstrated that the point in the œsophagus to be reached if necessary by the finger is not less than thirteen inches from the upper incisors or six from the cricoid cartilage, the operation of gastrotomy should be performed.

Inasmuch as the best argument in favour of gastrotomy is that the fingers may be used to detach the foreign body if all other means fail, it is evident that the probability of the introduction of the hand into the stomach is the most important element in the selection of the incision through the abdominal wall. In the case of the patient upon whom I have done this operation it seemed to me best to make an oblique incision under the margin of the ribs on the left side, directly over the stomach. By this incision the stomach can be recognised very easily, and drawn out of the wound so far that the subsequent manipulations can be made without the escape of the contents into the peritoneal cavity. From a large number of dissections for the purpose of deciding the question of incision in the abdominal wall, I have come to the conclusion that the oblique cut is the best on the whole for this operation, although the fingers can be introduced into the œsophagus with ease after making the median cut. The incision through the walls of the stomach for the purpose of introducing instruments into the cardiac end of the œsophagus may be made anywhere, provided that it is far enough to the right to avoid the convexity of the lesser curvature. All that is necessary is to put the lesser curvature on the stretch, so that it makes a straight line to the diaphragmatic opening. The cut through the stomach wall must be far enough to the right to allow the passage of the instrument along the sulcus between the anterior and posterior walls of the stomach, made tense as above. If the instrument is brought obliquely to this groove and passed upwards, all the time being pressed gently against the straightened lesser curvature, it will glide into the œsophagus every time with the greatest ease.

The incision in the median line was made on many subjects, and the conclusion was that it is the better method of operation where it is intended only to pass instruments into the œsophagus. In these observations it was found practicable to pass instruments into the œsophagus and withdraw coins with the greatest ease through an abdominal cut in the median line only two inches and a half in length. By enlarging the incision it was found to be quite practicable to introduce the hand into the stomach and pass the fingers into the œsophagus, but not so easy as by the oblique incision. It was also much more difficult to draw the stomach out of the peritoneal cavity enough to avoid the escape of the contents of the stomach into the abdominal cavity. The stomach having been exposed by the lateral cut through the abdominal walls, and having been drawn out of the wound, it must be held by an assistant in such a way that the lesser curvature is put on the stretch. It is better for the assistant to hold the stomach in both hands, so that the whole viscus is flattened out. He should stand on the left of the patient, and grasp the greater curvature. The operator standing on the right of the patient, holds the lesser curvature between the left thumb and forefinger, thereby making tense the lesser curvature and assisting in the passage of the instrument. Before doing this, it is best to introduce the hand into the peritoneal cavity and examine the diaphragmatic opening externally. With the stomach held as described, the opening through its walls may be made anywhere in the flattened surface, so as to avoid the large vessels. It goes without saying that the incisions should first be just large enough to get hold of the stomach with the thumb and fingers and draw it out so as to stretch the lesser curvature. An incision through the stomach wall can then be made large enough to introduce the instrument, by which, I believe, the foreign body can be removed with ease in the majority of cases. In cases of stricture of the œsophagus, the instrument can be passed with very small openings both in the abdominal walls and in the stomach itself. The wounds in the stomach and abdominal wall should be closed in the usual manner.

In the selection of the operation, whether by external œsophagotomy or by gastrotomy, another reason for the choice of the latter operation is that there is less danger of wounding important structures in the thorax, where the traction is downwards, than upwards. If the body is at the orifice, it is not in direct relation with either pleura, heart, or aorta. There is much less danger of lacerating the œsophageal wall in pulling down the foreign body a short distance than in pulling it up a considerable one. Finally, the prognosis after laparotomy and gastrotomy where the opening in the stomach is small I believe to be very good indeed. As to the frequency of the conditions requiring this operation, with the exception of impacted foreign bodies and stricture of the œsophagus, I know of no indication for the operation. It is certainly within the experience of nearly every surgeon that foreign bodies do become impacted low down in the œsophagus, and that the dangers which arise therefrom are very great. It is in the hope that in such cases this method which I have described will be tried that I submit these observations. Since Labbé's successful case in 1875 to the present time there has been no reported fatal case of laparotomy and gastrotomy for foreign body in the stomach. In the two fatal cases, one had been preceded by an external œsophagotomy, and in the other the stomach wall had been perforated by the foreign body. The list comprises the cases of Labbé, Cocher, Edioubom, Thornton, Billroth, Credé, Bernay, and Polaillon.

AN EXPERIMENTAL CONTRIBUTION TO INTESTINAL SURGERY.[1]

WITH SPECIAL REFERENCE TO THE TREATMENT OF INTESTINAL OBSTRUCTION.

BY N. SENN, M.D., PH.D., MILWAUKEE, WIS.,

ATTENDING SURGEON TO THE MILWAUKEE HOSPITAL; PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.

THE following is a synopsis of the paper:—

I. ARTIFICIAL INTESTINAL OBSTRUCTION.

1. *Stenosis.*—(*a*) Partial enterectomy and longitudinal suturing of wound. Traumatic stenosis from this cause becomes a source of danger from obstruction or perforation in all cases where the lumen of the bowel is reduced more than one-half in size. Longitudinal suturing of wounds on the mesenteric side of the intestine should never be practised, as such a procedure is invariably followed by gangrene and perforation by intercepting the vascular supply to the portion of bowel which corresponds to the mesenteric defect. (*b*) Circular constriction of intestine. The immediate cause of gangrene in circular constriction of a loop of intestine is due to obstruction of the venous circulation, and takes place first at a point most remote from the cause of the obstruction.

2. *Flexion.*—(*a*) Flexion produced by partial enterectomy and transverse suturing of wound. On the convex surface

[1] Read in the Surgical Section of the International Medical Congress held at Washington.

Digitized by Google

of the bowel a defect an inch in width can be closed by transverse suturing without causing obstruction by flexion. In such cases the stenosis is subsequently corrected by a compensating bulging, or dilatation of the mesenteric side of the bowel. Closing a wound of such dimensions on the mesenteric side of the bowel by transverse suturing may give rise to intestinal obstruction by flexion, and to gangrene and perforation by seriously impairing the arterial supply to, and venous return from, the portion of bowel corresponding with the mesenteric defect. (*b*) Flexion caused by inflammatory and other extrinsic causes gives rise to intestinal obstruction only in case the functional capacity of the flexed portion of the bowel has been diminished, or suspended by the causes which have produced the flexion, or by subsequent causes independently of the flexion.

3. *Volvulus.*—As in flexion, a volvulus gives rise to symptoms of obstruction when the causes which have given rise to a rotation upon its axis of a loop of bowel have at the same time produced an impairment or suspension of peristalsis in the portion of bowel which constitutes the volvulus, or when a diminution or suspension of peristalsis follows in consequence of the rotation.

4. *Invagination.*—Accumulation of intestinal contents above the seat of invagination is one of the most important factors which prevents spontaneous disinvagination, and which determines gangrene of the intussuscipiens. Spontaneous reduction is not more frequent in ascending than descending invagination. The immediate cause of gangrene of the intussuscipiens is obstruction to the return of venous blood by constriction at the neck of the intussuscipiens. Ileo-cæcal invagination, when recent, can frequently be reduced by distensions of the colon and rectum with water, but this method of reduction must be practised with great care and gentleness, as over-distension of the colon and rectum is productive of multiple longitudinal lacerations of the peritoneal coat, an accident which is followed by the gravest consequences. The competency of the ileo-cæcal valve can only be overcome by over-distension of the cæcum, and is effected by a mechanical separation of the margins of the valve; consequently, it is imprudent to attempt treatment of intestinal obstruction beyond the ileo-cæcal valve by injections per rectum.

II. ENTERECTOMY.

Resection of more than six feet of the small intestine in dogs is uniformly fatal; the cause of death in such cases is always attributable to the immediate effects of the trauma. Resection of more than four feet of the small intestines in dogs is incompatible with normal digestion, absorption, and nutrition, and often results in death from marasmus. In cases of extensive intestinal resection the remaining portion of the intestinal tract undergoes compensatory hypertrophy, which macroscopically is shown by thickening of the intestinal coats and increased vascularisation.

III. PHYSIOLOGICAL EXCLUSION.

Physiological exclusion of an extensive portion of the intestinal tract does not impair digestion, absorption, and nutrition as seriously as the removal of a similar portion by resection. Fæcal accumulation does not take place in the excluded portion of the intestinal canal. The excluded portion of the bowel undergoes progressive atrophy.

IV. CIRCULAR ENTERORRHAPHY.

A modification of Jobert's invagination suture by lining the intussusceptum with a thin flexible rubber ring, and the substitution of catgut for silk sutures, is preferable to Czerny-Lembert sutures. The line of suturing, or neck of the intussuscipiens, should be covered by a flap or graft of omentum in all cases of circular resection, as this procedure furnishes an additional protection against perforation. In circular enterorrhaphy, continuity of the peritoneal surface should be secured where the mesentery is detached by uniting the peritoneum with a fine catgut suture before the bowel is united, as this modification of the ordinary method furnishes better security against perforation on the mesenteric side.

V. INTESTINAL ANASTOMOSIS.

The formation of a fistulous communication between the bowel above and below the seat of obstruction should take the place of resection and circular enterorrhaphy in all cases where it is impossible or impracticable to remove the cause of obstruction, or where the pathological conditions which have given rise to the obstruction do not constitute an intrinsic source of danger. Gastro-enterostomy and jejuno-ileostomy should always be made by approximation with partially or completely decalcified perforated bone plates. In making an intestinal anastomosis for obstructions in the cæcum or colon, the communication above and below the seat of obstruction can be established by apposition with decalcified perforated bone plates, or by lateral implantation of the ileum into the colon or rectum. An ileo-colostomy, or ileo-rectostomy by approximation with decalcified perforated bone plates or lateral implantation should be done in all cases of irreducible ileo-cæcal invaginations, where the local signs do not indicate the existence or occurrence of gangrene and perforation. In all cases of threatened gangrene and perforation, the invaginated portion should be excised, both ends of the bowel closed, and the continuity of the intestinal canal restored by making an ileo-colostomy by approximation with perforated decalcified bone plates, or by lateral implantation. The restoration of the continuity of the intestinal canal by perforated approximation plates or lateral implantation should be resorted to in all cases where circular enterorrhaphy is impossible on account of the difference in the size of the lumina of the two ends of the bowel. In cases of multiple gunshot wounds of the intestines involving the lateral or convex side of the bowel, the formation of intestinal anastomosis by perforated decalcified bone plates should be preferred to suturing, as this procedure is equally if not more safe, and requires less time.

VI. ADHESION EXPERIMENTS.

Definitive healing of an intestinal wound is only completed after the formation of a network of new vessels in the product of tissue proliferation from the approximated serous surfaces. Under favourable circumstances, quite firm adhesions are formed between the peritoneal surfaces within from six to twelve hours, which effectually resist the pressure from within outwards. Scarification of the peritoneum at the seat of approximation hastens the formation of adhesions and the definitive healing of intestinal wounds. Omental grafts, from one to two inches in width, and sufficiently long to completely encircle the bowel, retain their vitality, become firmly adherent in from twelve to eighteen hours, and are freely supplied with bloodvessels in from twenty-four to forty-eight hours. Omental transplantation or omental grafting should be done in every circular resection or suturing of large intestinal wounds, as this procedure favours the healing of the visceral wound, and furnishes an additional protection against perforation.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

MIDDLESEX HOSPITAL.

THREE FATAL CASES OF NON-TROPICAL DYSENTERY.

(Under the care of Dr. CAYLEY and Dr. FINLAY.)

THE occurrence of non-tropical dysentery in England is so rare that the following cases will be found of interest. The liver does not appear to have been affected in any of these cases, but we have seen a case in which the disease (non-tropical) ran an acute course, and was attended with large hepatic abscess. For the subjoined notes we are indebted to Dr. Pasteur, medical registrar.

CASE 1.—Florence H——, aged nineteen years, single, was admitted on May 20th, 1886. Her grandfather on the mother's side died of phthisis, and her father's parents both died of bronchitis. Her previous health had been excellent, and she had never lived out of England. About a year ago she became subject to sore-throat, and her tonsils became enlarged. On the advice of her doctor she had the right tonsil removed. The hæmorrhage from the operation was severe, and did not cease completely for a week, the patient

Digitized by Google

becoming much enfeebled by loss of blood. About three months previously to admission she began to suffer from constipation, and noticed blood in her motions at intervals, which had considerably increased of late.

On admission she was very anæmic, and complained of dyspnœa on the least exertion and loss of blood per anum, both during stool and in the intervals. There was sometimes pain in the lower abdomen and flanks. The abdomen was slightly distended and tense, with tenderness below the umbilicus. There was nowhere dulness or sense of local resistance, nor were there any signs of external piles. The liver and spleen were not felt below the ribs. The tongue was moist and slightly furred, the appetite good, and the bowels confined. The temperature was raised about one degree. The heart and lungs were perfectly healthy.

Progress and termination.—The first two stools passed consisted of clotted blood and mucus, and were accompanied by a good deal of pain. A rectal examination was made on May 25th, which revealed a circle of bleeding points (? minute polypi) about an inch above the internal sphincter. The previous night there had been severe abdominal pain, which necessitated the use of anodyne fomentations. The bowels acted on an average seven or eight times daily, the stools consisting almost entirely of blood. On the 26th the rectal speculum was again introduced, and the exposed bleeding points and "ulcers" freely dusted with powdered persulphate of iron, followed by a morphia and tannic acid suppository. By the mouth, chalk, catechu, and opium.

On May 27th she was transferred to the care of Mr. Henry Morris, who examined the rectum on the following day under ether and cauterised the bleeding ulcers, at the same time stretching the sphincter ani. Ergot was given twice daily, and a starch enema, with opium, catechu, and krameria when necessary. Three motions took place in the next twelve hours. The enema was administered three times.

May 31st.—Had persistent diarrhœa the whole of yesterday, the motions containing a little blood. Evening temperature above 101°.

For the next nine days the patient continued to get progressively weaker, the diarrhœa proving quite intractable. The pulse increased in frequency (100 to 140), and was at times intermittent. Blood continued to be present in most of the stools. The fæcal matters passed were light-coloured, but not particularly offensive. The evening temperature was on an average 102°, with a morning remission of about two degrees. The abdomen was tympanitic and considerably more distended than on admission, and occasionally very painful. Hot fomentations were employed continually. The tongue was smooth and raw-looking. On June 8th and following days there was troublesome ulceration of the mouth. On the 13th the mouth was better, but otherwise there was no change in the patient's condition. Towards evening she became rather suddenly collapsed, without increase of abdominal pain. She rallied somewhat with stimulants, but the stomach had become intolerant of all food, and death occurred the following evening.

Necropsy, thirty-eight hours after death.—Body fairly nourished. Heart and lungs healthy. Liver swollen and cloudy. Spleen very slightly enlarged. Kidneys apparently quite healthy. Abdomen: Cæcum and large intestine distended; mesenteric glands enlarged. Intestine: There were signs of catarrh at the lower end of the ileum, with injection of the mucous membrane, but no signs of ulceration. The caput cæci was free from ulceration, but throughout the remainder of the large bowel the mucous and submucous tissue was extensively destroyed, leaving only irregularly rounded islets of mucous membrane here and there. Over the intervening areas the muscular coat of the bowel was seen clean and free from slough. At the upper part of the rectum there was an area of about two inches in length almost free from ulceration, but at the margin of the anus a large ulcer was present, laying bare the muscular coat. Near this were several smaller ulcers. Some of the islets of mucous membrane showed bright injection at their margins. The muscular coat of the bowel was thickened throughout.

CASE 2.—Mary P——, aged twenty-three years, single, housemaid, was admitted on June 22nd, 1886. Twelve months previously she began to pass small quantities of blood at stool, without pain. This disappeared under medical treatment, and did not return until January, 1886. Since that date, however, the condition became aggravated. The act of defecation was preceded and followed by severe pain, and the quantity of blood lost was considerably greater than at first. On examination there were no external piles, but on introducing the finger into the rectum it was found to be much dilated above the internal sphincter, but not tender.

On admission to a medical ward at the beginning of July the temperature was subnormal; the pulse was soft and dicrotic (108); and anæmia and emaciation were both marked. The thoracic viscera were healthy. The liver dulness measured five inches vertically in the right nipple line, and the spleen was of normal size. There was tenderness in the epigastric and in both hypochondriac regions. A motion passed on July 6th was loose, of normal colour, streaked with blood, and not particularly offensive. Ordered to take lead and opium pill (four grains) three times a day.

During the next three days the bowels were moved three times daily, the motions containing a considerable quantity of altered blood. Was sick repeatedly on the night of July 9th. Pills discontinued. To be fed entirely by nutrient enemata and suppositories.

July 12th.—Feels better. Character and frequency of motions unchanged. Pulse very dicrotic.

17th.—Continues better. Diarrhœa as before, but no blood in stools.

19th.—Six motions containing blood.

25th.—Stools occasionally contain blood. Frequent sickness. Wasting rapidly. Ordered, ipecacuanha powder in full doses; iced champagne and mutton broth.

27th.—Sickness less. Motions as before, with the addition of membranous shreds and blood. Complains of slight abdominal pain.
